Prof. L. Gilchrist presented a paper on resistivity measurements at the Chickamauga Dam site, Tennessee, where underground caverns were located by the proper use of 'Megger' instruments. A survey of methods used to determine overburden above magnetic deposits by magnetic methods with field examples was given by Prof. D. A. Keys. Dr. W. H. Martin dealt with the Raman spectra of some oximes, and pointed out the shift of one Raman line due to addition of hydrochloric acid to certain amines and to mercuric chloride in solution. Prof. J. A. Gray gave the results of the scattering of X-rays at small angles by charcoal, and presented further evidence that some β -rays lose energy when scattered through large angles by nuclei.

The Rev. A. Vachon presented an interesting account of the salinity of the water at different points in the estuary of the St. Lawrence River; from these measurements, arctic currents can be traced, especially along the north shore, and also the course of the water from the Saguenay after it enters the St. Lawrence. Prof. E. H. Boomer, speaking on

phase equilibria in hydrocarbon systems, showed that the behaviour of the systems relative to one another can be predicted qualitatively from the chemical and physical properties of the liquid hydrocarbons used. Results of experiments by Prof. C. C. Coffin on the effect of molecular structure on the rate of unimolecular gas reactions show that the replacement of hydrogen by chlorine atoms produces a slight decrease in rate, while introduction of a double bond gives a fourfold increase. Prof. W. Lash Miller presented a group of papers on Wilders' bios and yeasts. Of fourteen papers presented by Prof. O. Maass and his students, one on the measurement of the specific heat of propylene in the critical pressure - critical temperature region contained an account of a new type of adiabatic calorimeter, and it was shown that the liquid state of aggregation persists above the critical temperature. Prof. H. Hibbert (with F. B. Pickett and G. F. Wright) reported on the relative acidity of carbohydrate hydroxyl groups; they find that the hydroxyl group attached to the C_4 atom in glucose is more acid than those attached to the C_1 , C_2 and C_3 atoms.

Prof. W. H. Watson presented a paper on the electron and the limits to the precision of electromagnetic field specifications, in which the uncertainty relations of the electromagnetic field are applied to determine the corresponding uncertainties in the motion of an electron in the field. Prof. J. L. Synge presented several papers by his associates, of which one on the problems of the beam and the plate in the theory of elasticity, by J. N. Goodier, was of particular interest, as it proved that the engineering theories of beams and plates are good to a high order of approximation under the conditions of use. Prof. A. F. Stevenson gave a paper on a generalization of Oseen's equations for steady flow past a fixed obstacle, with application to the sphere, and Prof. R. L. Jeffery another on sequence integration and non-absolutely convergent integrals for functions of two or more variables. A paper by Prof. W. L. G. Williams and M. S. MacPhail on functions of the complex variable $z = x + jy$, where $j^2 = -1$, was of particular interest, and mention may also be made of a paper by Prof. S. Beatty and D. C. Murdoch on routine for determining the numbers e, m associated with a cycle $f = \alpha(p)$ of an algebraic equation $F = 0$.

Prof. H. A. McTaggart demonstrated the ellipticity of the light reflected at the surface of films of oriented molecules. Prof. A. L. Clark gave the result of the experimental determination of the probability of a steel ball falling through one of a number of holes in a plate. Prof. E. F. Burton presented a number of papers describing work done in the McLennan laboratories. The specific heat of tributyrin at low temperatures has been measured by J. O. Wilhelm and A. H. Woodcock, who find that it varies from 0.4 cal./gm. at room temperature to 0.012 at 16° K. H. E. Johns and J. O. Wilhelm have determined the refractive indices for λ 5461 Å. of liquid oxygen (1.2242), liquid nitrogen (1.1990) and liquid hydrogen (1.1120). J. M. Anderson has determined the half

lives of several lines in the spectrum of argon II by a modified canal-ray method; all so far measured have a half life of less than 10^{-8} second.

In the Geological Section (4) eighteen papers were presented. Three new fellows were elected: Dr. G. W. H. Norman, of the Geological Survey of Canada; Prof. F. F. Osborne, of McGill University, and Dr. J. F. Walker, provincial mineralogist of British Columbia. Among the interesting papers presented the following may be mentioned.

Prof. G. H. Handerson (of Section 3) described two new types of pleochroic haloes in biotite, and showed that they are invariably associated with minute fissures through the mineral. He indicated that they originated from certain members of the radium family of very short life-period, and suggested that precipitation of minute grains of radium-bearing minerals from the fissure-filling solutions probably accounts for the localization of the haloes.

The last paper of the late Dr. W. H. Collins, formerly director of the Geological Survey of Canada, was presented by H. C. Horwood, who had assisted him with much of his field work. Results of several years of detailed study of the Sudbury district strongly confirm the original conclusions of Dr. A. P. Coleman as to the magmatic origin of the ores, and indicate that secondary processes play a relatively minor part in ore deposition. Dr. Coleman, now eighty-five years of age, was present at the meeting to hear this vindication of his conclusions.

H. C. Cooke presented new data on the age of the Dore series of Michipicoten district, Ontario, based on determinations of the structure of the Keewatin lavas, and concluded that the Dore series is probably of Temiskaming age, and is not interbanded with the Keewatin as previously supposed. W. C. Gussow presented the results of his work during tenure of one of the Carnegie fellowships administered by the Society. These indicate that the gold deposits of the Rouyn area, Quebec, are not primarily related to the granitic stocks, but were deposited from soda-bearing solutions introduced along fissures at some later date. The solutions albited the intrusives and caused profound petrographic changes in them.

In Section 5 (Biological Sciences) sixty papers were presented, in part before the whole section, and in part to two subsections (Zoology and Botany, and the Medical Sciences). Profs. D. L. Bailey and G. F. Marrian of the University of Toronto and Dr. J. H. McDunnough, of the Division of Systematic Entomology of the Dominion Department of Agriculture, were elected fellows of the Section.

Prof. E. M. Walker gave the sectional presidential address on "*Grylloblatta*, a Living Fossil", and showed a very interesting cinematograph film of this prehistoric beetle from the Canadian Rockies, proving, *inter alia*, that the heat of the hand rapidly causes its complete prostration, while contact with ice leads to slow recovery. Prof. A. G. Huntsman traced the cause of the scarcity of salmon which occurs periodically in the Atlantic provinces every nine or ten years, as due to a succession of dry summers (also occurring periodically) which result in such lowering of the water of salmon streams that the young salmon parr are clearly exposed to kingfishers and mergansers, which take an unusually large toll. He also communicated an account of W. H. Johnson's study of the effect of light on the marine copepod *Acartia clausi*, which shows that movement is brought about by changes in intensity

of light (upwards with diminution, downwards with increase of intensity), rather than by the degree of intensity itself; under static light conditions, the animals gradually become uniformly distributed.

Dr. J. W. MacArthur reported from his studies of finger and palm prints that left and right hands are as different in identical as in fraternal twins while hands of the same side are quite similar in identical twins, but show large and increasing differences in the series: fraternal or sib pairs parents and children, and unrelated persons. By such comparisons, the twin type can be correctly diagnosed in about half the pairs from their own prints alone, and in nearly all when prints of their parents and sibs are also available.

Prof. G. W. Searth presented a paper by D. Siminovitch showing that the cells of plant tissues frozen internally with intra-cellular ice formation always die, while those dehydrated by external (inter-cellular) ice will survive, even after extreme dehydration of the protoplasm. Prof. Marie-Victorin and the Rev. J. Rousseau gave a paper extending the former's theory of the development of the flora of the St. Lawrence valley. R. B. Thomson described comparative studies of the 'inverted' bundles of male and female cone scales in a series of conifers, confirming the view that these are homologous structures which during growth come to assume different positions in association with the function of the scales as sex organs. Prof. W. P. Thompson presented several papers by himself and co-workers dealing with genetic problems in wheat and other cereals. Prof. A. H. R. Buller reviewed the life-history of the wheat rust, and reported new discoveries concerning the fusion in pustules on the barberry leaf of pycnia with a hypha of opposite sign.

Prof. J. W. MacArthur presented a paper by C. K. Gunn giving an account of a strain of rats which has, as a monofactorial autosomal recessive mutant character, acholuric jaundice resembling that in man in its chief clinical and genetic features. A paper by A. E. Allin (presented by Prof. D. T. Fraser) showed that, in general, skin sensitivity to diphtheria toxoid develops within three weeks during an attack of diphtheria in those who are initially non-sensitive, and increases at this time in those initially sensitive in some degree.

Prof. G. F. Marrian (with G. C. Butler) showed that an ether-soluble fraction from two women with adrenal tumours contained unusual amounts of pregnandiol, and also a triol, $C_{21}H_{36}O_3$, melting at $243-244^\circ$ C. R. G. Sinclair adduced evidence that the red blood cells of the dog and the cat do not take part in fatty acid transport. E. G. Young gave an interesting account of prolonged study of purine metabolism in the Dalmatian coach hound from early age to adolescence.

Prof. C. C. MacKlin described the detailed histology of the pulmonary alveolar walls of the adult cat, illustrating his paper by beautiful slides from photomicrographs, and stressed the presence of many 'bare areas' devoid of nuclei.

Prof. F. G. Banting presented a number of papers from workers in the Banting Institute of the University of Toronto. W. R. Franks and H. J. Creech have succeeded in forming chemo-antigens by coupling 1:2:5:6-dibenzanthracene and similar compounds to proteins, and injecting the products into rabbits, guinea pigs, and rats; formation of haptene specific antisera was demonstrated by precipitin reactions and by specific inhibition with

the prosthetic substances. H. F. Richardson showed that death from intra-venous air embolism in dogs depends on the rate of injection; at very slow rates surprisingly large amounts of air can be injected before death ensues (through failure of the pulmonary circulation). B. C. Coles showed that the type of oath in cases of criminal abortion, commonly ascribed to small amounts of air found in the heart post-mortem, may be due rather to lethal amounts

of toxic substances (such as potassium soaps) in the douche solution having entered the blood stream from the uterine cavity. According to D. Irwin, the tissue response to different samples of quartz is practically identical. W. R. Franks, L. D. Proctor and A. Duncan described a photo-electric dust estimator, designed to measure accurately and rapidly dust retainable by the lungs and therefore to estimate the dust hazard.

Recent Aeronautical Research

THE report of the Aeronautical Research Committee, issued recently*, deals with a period of nearly two years, from April 1935 until December 1936. This is to cover a change of procedure, future reports being issued for the calendar year. The report opens with a well-merited tribute to the memory of Sir Richard Glazebrook and Sir Joseph Stetavel, who died during the period under review. They were both original members of the Advisory Committee for Aeronautics, appointed in 1909, and all who have had any connexion with aeronautics will appreciate how much the development of the science owes to them.

The outstanding feature of the period under review has been the increase in, and the still further demands for, high performance of aircraft. The major part of the Committee's activities are obviously directed towards this object. It is emphasized that the more recent equipment at the National Physical Laboratory and the Royal Aircraft Establishment, although elaborate and expensive, have made possible advances in the fundamentals of aircraft aerodynamical design to an extent that could never have been accomplished by the trial-and-error methods of full-scale experimental flight alone. The compressed air tunnel and the one-foot high-speed tunnel at the former, and the 24-ft. wind tunnel at the latter, are cases in point.

The 24-ft. tunnel at the R.A.E. has been used principally for the investigation of engine-cooling problems. At high translational speeds, theory shows that it should be possible to provide enough cooling without adding at all to the drag of the complete aeroplane, and this prediction has been supported by experimental results. As the induced drag at high speeds is very small, it follows that a well-designed aircraft travelling at high speed need have a drag very little higher than that due to the friction between its exposed surfaces and the air.

Aeroplane speeds are now almost approaching the range in which compressibility becomes important, and the Committee, by undertaking research on compressibility effects, is taking steps to have information available by the time it is required. The apparatus used for this work is a one-foot high-speed tunnel, run from the exhaust of the compressed air tunnel. Tests on thick aerofoils have been done, and suggest that it may be necessary to take account of compressibility drag when speeds of flight exceed four hundred miles per hour.

Much of the time of the compressed air tunnel has

been devoted to investigations of surface friction. At the Reynolds numbers of flight a surface roughness corresponding to excrescences of the order of one-thousandth of an inch in height may be enough to increase the friction substantially. This measure of roughness is inappreciable at Reynolds numbers corresponding to those in ordinary atmospheric tunnels, so that although roughness may produce a difference in the behaviour of an actual aeroplane, the cause was not appreciated until this problem had been worked out.

Drag measurements have also been made in flight by means of a comb of small pitot tubes which determine the difference in relative velocity between the air in the wake of the wing and the free air. It can also be applied in the compressed air tunnel, which will enable profile drag to be determined at Reynolds numbers of the order of those reached by fast modern aeroplanes.

Another problem has been to determine where on aeroplane wings the change from laminar to turbulent flow in the boundary layer takes place. As the drag associated with the turbulent boundary layer is considerably greater than that of the laminar layer, it is important to keep the transition point on the wing as far back as possible. It is suspected that protuberances in the surface of a wing near its leading edge may promote an early transition point and so increase the drag.

Modern high-speed machines have introduced other problems, particularly of stability. For example, directional stability is often unexpectedly good, although longitudinal stability is not so satisfactory. Further, increasing speed inevitably implies higher wing loading and thus introduces landing problems. The properties of flaps and other aids to stability, particularly when landing and taking off, have been studied, and work on gusts in the atmosphere is continuing.

Structural problems following upon the recent development of 'stressed skin' bodies and wings have shown that stabilizing members for flat, or slightly curved, sides of bodies need to be carefully studied for optimum efficiency. Tubular members are stronger for a given amount of material, but their use presents practical difficulties.

In aero-engine work, attention has been paid to the development of bi-fuel systems, which at the moment appear to be necessary with the use of 100 octane fuel. Direct fuel injection, supercharging, high boiling point liquids for cooling, spark ignition, and the compression ignition engine have been subjected to investigation in various details, but nothing revolutionary is proposed.

* Aeronautical Research Committee. Report for the years 1935-36. p. 60+7 plates. (London: H.M. Stationery Office.) 4s. net.

The question of the size of sea-going aircraft has been studied in a general way, and the Committee expresses the opinion that no new scientific problem seems probable with flying boats of up to a hundred tons in weight.

The technical supplement to the report is sub-

divided into sections dealing with: aerodynamics, fluid motion, stability and control, oscillation, spinning structures, elasticity and fatigue, alloys, engines, aircraft noise, seaplanes, meteorology, accidents, administration including (a) list of publications and (b) membership of sub-committees and panels.

"Discovery" Investigations*

DURING the years 1935 and 1936 three volumes have been published containing reports on material collected by the "Discovery" expeditions, on many subjects by various workers. Vol. 11 is devoted entirely to plankton, and forms an introduction to the study of the plankton of the Antarctic, embodying as it does, a detailed discussion of methods and their value, besides extensive accounts of the distribution and migrations of plant and animal plankton, pre-eminently important for the understanding of the natural history of the Blue, Fin, Sei and Humpback whales. It is noteworthy that the first instance of vertical migration of phytoplankton is here shown in certain species of *Oscinodiscus* which ascend during the daytime, the reverse of the usual animal migration. It is constantly seen in the "Discovery" reports that *Euphausia superba* appears to be a key animal with regard to the distribution of Antarctic plankton, forming directly the food of the Blue and the Fin whales, and indirectly influencing the plankton in a variety of ways. A consideration of the relationship between the distribution of the whales and that of the plankton, and between the zooplankton and the phytoplankton, has led to the recognition of certain general principles of pelagic ecology.

The remarkable patchiness in distribution of many of the plankton animals is emphasized, and Prof. Hardy's hypothesis of animal exclusion, showing that the more important plankton animals avoid the areas of dense phytoplankton, is dwelt upon at length. In this connexion, the phosphate values are shown to be of extreme importance, and relative reduction in phosphate content appears to be a better index in studying the zooplankton relationship than the phytoplankton itself, giving a measurement of phytoplankton over a little time in the past. The appearance of exclusion from regions of low phosphate (high phytoplankton) applies to animals belonging to widely different groups, and it is considered that if the distribution of the animals is being modified by the phytoplankton, this modification must be brought

about by variations in the vertical migration in conjunction with differing water movements at different levels. All the animals which show the exclusion effects have marked vertical migrations. This first report is intended to form an introduction to pelagic ecology of the Antarctic seas. The plankton community is considered in relation to its hydrological background, and to the distribution of the Blue and Fin whales which feed upon the plankton and form the object of such an important fishery in these seas.

The second plankton report deals with the continuous plankton recorder invented by Prof. Hardy. This has now been much improved, and a full account is given of its construction, method of working and the advantages and limitations of the results obtained in its use. The third paper deals with observations on the uneven distribution of oceanic plankton, and describes records of plankton taken in the open ocean during the voyages of the R.R.S. *Discovery* and R.R.S. *William Scoresby* in the years 1925-27, with the original form of continuous plankton recorder. They were made with the view of studying the main fluctuations in the planktonic density along uninterrupted lines of observation. These lines varied from 23 miles to more than 100 miles in length, and were made in different oceanic regions from the tropical to the antarctic zone. The records demonstrate marked fluctuations in the distribution of the main planktonic groups of animals, no less marked in the tropics than in the antarctic zone. The existence of a rhythm in the distributional fluctuations is tentatively suggested, a rhythm which varies on different occasions.

Vol. 12 embodies a variety of subjects, the first being the coast fishes from the South Atlantic by J. R. Norman. The term 'coast fishes' includes not only the littoral forms, but also fishes that may occur at no great distance from the coasts in water down to two or three hundred fathoms deep, and that are not pelagic or bathypelagic. C. C. A. Munro continues his description of the polychaete worms (2), Dr. Th. Mortensen reports on the Echinoidea and Ophiuroidea, R. A. B. Ardley on the birds of the South Orkney Islands and Dr. R. Gurney begins his study of the decapod larvae (Stenopidea, Amphionidea and Phyllosoma).

In Vol. 13 A. Earland continues the Foraminifera (4), R. A. B. Ardley describes the R.R.S. *Discovery II*, its construction and design, accommodation for research, scientific equipment and laboratory methods, E. R. Gunther writes on oceanographical investigations in the Peru coastal current, and Dr. F. D. Ommanney contributes an extensive paper on the copepod *Rhincalanus gigas* (Brady) which is very important in Antarctic waters and is reported on fully in every aspect as a representative plankton animal in these regions.

* Discovery Reports. Issued by the Discovery Committee, Colonial Office, London, on behalf of the Government of the Dependencies of the Falkland Islands. Vol. 11. The Plankton of the South Georgia Whaling Grounds and Adjacent Waters, 1935-1937. By A. O. Hardy and H. B. Gunther. Pp. iv+456. 50s. net. The Continuous Plankton Recorder. By A. O. Hardy. Pp. 457-510+4 plates. 9s. net. Observations on the Uneven Distribution of Oceanic Plankton. By A. O. Hardy. Pp. 511-538. 4s. net. Vol. 12. Coast Fishes, Part I: The South Atlantic. By J. R. Norman. Science News a Century Ago

A Pigmy Cemetery

THE issue of the *Gentleman's Magazine* of August 1837 contains the following information: "A short distance from Cochocton, Ohio, U.S., a singular ancient burying-ground has lately been discovered. It is situated, says a writer in *Silliman's Journal*, on one of those elevated, gravelly alluvions, so common on the rivers of the West. From some remains of wood, still apparent in the earth around the bones, the bodies seem all to have been deposited in coffins; and what is still more curious, is the fact that the bodies buried here were generally not more than from three to four and a half feet in length. They are very numerous, and must have been tenants of a considerable city, or their numbers could not have been so great. A large number of graves have been opened, the inmates of which are all of this pigmy race. No metallic articles or utensils have yet been found to throw light on the period or the nation to which they belonged."

Monument to Gutenberg

THREE hundred and sixty-nine years after his death, a large statue in bronze of Gutenberg, the inventor of printing from movable type, was unveiled at his birthplace, Mainz, the inaugural proceedings extending over the three days, August 14-16, 1837. The statue was by the Danish sculptor Thorwaldsen, and it bears the inscription "Joannem Gensfleisch de Gutenberg Patricium Moguntinum, ere per totam Europam collato posuerunt cives 1837".

Hare and the Oxy-hydrogen Blow-pipe

ON August 14, 1837, Prof. Robert Hare (1781-1858) wrote from Philadelphia to Dalton, saying: "I beg leave, through you, to communicate to the British Association for the Advancement of Science, the fact that by an improvement in the method of constructing and supplying the hydro-oxygen blow-pipe, originally contrived by me in 1801, I have succeeded in fusing into a malleable mass, more than three-fourths of a pound of platina. In all, I fused more than two pounds fourteen ounces into four masses averaging, of course, nearly the weight above-mentioned." After further notes on the application of the blow-pipe, he said: "I need not say how much I regret that the Atlantic rolls now between myself and those respected and esteemed brethren in science, whom, this time last year, I had the honour and pleasure to meet and to greet at Bristol, and to whom I shall ever be grateful for their kind reception. How much would it gratify me, could I exhibit to them, and their enlightened visitors, that splendid concentration of heat and light which I have lately employed, by which a metal infusible in the air-furnace or forge is made as fluid as mercury, so as to be blown off in globules."

Gossage and the Alkali Industry

ON August 17, 1837, William Gossage secured a patent for "certain improvements in the processes of operation connected with the manufacture of alkalis from common salt"; a patent which anticipated the later and successful processes of Weldon, Mond and Chance for the recovery of manganese and sulphur. Gossage, who was born in 1799, had begun

life in a chemist's shop at the age of twelve years; but by 1830 was a partner in a salt and alkali works at Stoke Prior, Worcestershire, and it was there that in 1836 he invented the 'Gossage' condensing tower for preventing the escape of hydrochloric acid gas, a "simple contrivance which saved from extinction a trade, the growth of which has contributed largely to the nation's prosperity". From Stoke Prior Gossage removed to Birmingham, establishing there a white lead works, and then to South Wales, where he engaged in copper smelting. In 1850 he settled at Widnes and became the largest soap manufacturer in the country. In 1861 he contributed a paper on "The History of Alkali Manufacture" to the Manchester meeting of the British Association. He died at Bowden, Cheshire, on April 9, 1877 (see "Some Founders of the Chemical Industry" by J. F. Allen).

The Magazine of Zoology and Botany

THE *Athenaeum* in its issue of August 19, 1837, referring to the above journal, which was conducted by Sir William Jardine (1800-1874), P. J. Selby (1788-1867) and Dr. G. Johnson, said: "To the naturalist this periodical affords a most valuable repository of the current facts and opinions of writers upon all points relating to zoology and botany; and it quite answers to our notion of what such a production should be, if it be of great general utility. There are excellent original papers by Swainson, Henslow, Westwood and other men of high scientific reputation, independently of the authors whose names stand upon the title page; there is a brief and very honest indication of the most interesting matters treated of in other periodical works on natural history, well brought down to the period of publication; and to these are added well-written sensible critiques on many of the more important works upon this branch of knowledge. Moreover, and this is not to be overlooked—the botanical department is conducted with reference to modern views and with a commendable disregard of prejudices."

University Events

CAMBRIDGE.—Dr. J. H. Schulman, of Trinity Hall, has been appointed assistant director of research in colloid science.

D. J. Bauer, of Trinity College, has been elected to the Michael Foster studentship in physiology; the E. G. Fearnside scholarship is awarded to A. M. Barry, of Pembroke College; the Wrenbury scholarship is awarded to P. T. Bauer, of Gonville and Caius College; the John Winbolt prize is awarded to D. W. Ginns, of Emmanuel College, for a dissertation on "The Mechanical Properties of some Metals and Alloys broken at Ultra High Speeds".

G. H. A. Wilson, master of Clare College, vice-chancellor of the University, has been appointed, in succession to the late Sir E. C. Hoskyns, to represent the University on Sept. 27-28 at the four-hundredth anniversary of the foundation of St. Mary's College in the University of St. Andrews. Dr. F. W. Aston and Dr. J. D. Cockcroft have been appointed to represent the University in Bologna on October 18 at the celebration of the bicentenary of the birth of Galvani. Prof. R. G. W. Norrish and Dr. J. D. Cockcroft have been appointed delegates from the University to a congress to be held at the Palais de la Découverte, Paris, on September 30-October 7.

Societies and Academies

Dublin

Royal Irish Academy, June 14

JOSEPH ALGAR and ISABELLA P. CARRY: The synthesis of flavonols: oxidation of flavindogenides. The oxidation in acetone solution of the flavindogenide 3-benzylidene flavanone by means of acidified potassium permanganate appears to give 3-hydroxy-3-benzoyl flavanone (I). The latter forms a monoxine and a monoacetate. Gentle hydrolysis of (I) gives flavonol and benzoic acid. Products similar in constitution to (I) are obtained by the oxidation of the following flavindogenides: 3-anisylidene flavanone; 3-piperonylidene flavanone; 3-benzylidene-3',4'-methylenedioxy flavanone.

H. S. W. MASSEY: Creation of electron pairs by nuclear capture of neutrons. The probability of creation of electron pairs by the materialization of the energy freed in the capture of a neutron by a nucleus is calculated by a method not involving explicit introduction of light quanta.

C. B. MORRAT: The mammals of Ireland. A catalogue is given of the species supposed to have any claim to inclusion in the fauna, with notes on the distribution and status of each. The list differs from Thompson's in including a much larger number of marine (chiefly oceanic) animals. Novelty among terrestrial mammals are few. They include, however, the Irish stoat (*Mustela hibernica*) and the Irish hare (*Lepus hibernicus*), both now marked as practically endemic. Three bats have been added to Thompson's list. There are also five new species of Rodentia. The pine-marten (*Martes martes*), is still known from ten counties; and the red deer (*Cervus elaphus scoticus*), though now confined as a strictly native species to a protected area in Kerry, has recently been shown to be living a perfectly wild life in a new home to which it has found its way among the Wicklow Mountains. The question of the admissibility of the wild cat (*Felis silvestris*) to a historic place in the Irish fauna is regarded as having been lately placed by Major Barrett-Hamilton in a new light.

Edinburgh

Royal Society, Edinburgh, July 5.

C. FORSTER-COOPER: The Middle Devonian fish fauna of Achanarras. This is the first section of a report on five seasons work in the flagstone quarry of Achanarras in Caithness and deals with the fishes of the genus *Dipterus*. Hitherto two forms, *Dipterus valencianesi* and *D. platycephalus* have been considered as separate species differing in the structure of the scales and in the extent to which the skull is ossified. It is now shown that the difference is due to seasonal changes, as described by Westoll for the contemporary Crossopterygians, and that the two conditions alternate during the life of the fish, so that there is only one species represented and not two. The abundance of material has rendered possible a full restoration of the fish.

FLORA COCHRAN: A histological analysis of eye pigment development in *Drosophila pseudo-obscura*. A detailed examination of unstained histological sections of the eyes of wild type and various mutants of *D. pseudo-obscura* at various stages of development was made. This revealed that pigment in the form of granules appears in two types of pigment cells at two definite times during development

and that genes which alter the colour of the eyes do so by affecting these granules in three distinct ways: (1) by suppressing the formation of all or part of the granules laid down in one or both types of pigment cells during either or both phases of development; (2) by altering the rate of granule development; (3) by causing a qualitative change in the granules.

A. R. WATERSON and H. E. QUICK: *Geonemertes dandyi* Dakin, a land nemertean in Wales. Since 1935, a land nemertean had been known from several localities near Swansea. The external and internal characters are described. Details are given of the habits, mode of feeding, and reproduction. The habitats are all damp places near streams or trees, and the nemerteans occur under stones and fallen branches. The sites seem to be free from contamination from exotic sources. Land nemerteans have not previously been found living under natural conditions in Europe.

R. S. BROWN: The anatomy of *Ophelia cluthensis* McGuire. An account of a polychaete worm which seems to be fairly common in the sand just below high water neap tide, not only in the Clyde estuary, from where it was originally described, but also in other parts of Great Britain and northern Europe. The species was created by McGuire in 1935, but her description was very incomplete, and the present account gives much fuller details of its specific characters and also a discussion of its affinities with other members of the genus. The description of the anatomy includes an account of the lymphatic corpuscles, which in this genus consist of two types of cells: (i) small disk-shaped cells 15–20 μ in diameter, with radiating processes; and (ii) larger irregular cells, 40–150 μ in diameter, containing a dense central body usually in the form of a club. Reproductive cells are also found in the coelomic fluid.

Paris

Academy of Sciences, June 14 (C.R., 204, 1769–1848).

ANDRÉ BLONDEL: The search for short light signals by navigators. Discussion of the effects of the duration of the light signals from the physiological point of view.

GEORGES CHARPY: The definition of the *nuance* of steels.

JACQUES DE LAPPARENT: The mineralogical nature of the clays of El Golea (Sahara).

OTOKAR BOBŮVKA: Multiplicative systems.

MICHEL GHERMANESCU: A problem of Laguerre.

RICHARD BRAUER: The multiplication of the characteristics of continued and semi-simple groups.

KUNTSMANN: Multiform operations. Hypergroups.

M. KELDYCH and MICHEL LAVRENTIEFF: The problem of Dirichlet.

P. DUPUIS, H. GUILLEMET and ANDRÉ MARTINOT-LAGARDE: The determination of the trajectories of the water particles in the flow through a centrifugal pump.

JACQUES VALENSI: A new method for the measurement of the delivery through a tube placed in a current of air of uniform velocity.

RENÉ HIRSCH: The automatic stabilization of aeroplanes.

PIERRE AUGER, PAUL EHRENFEST, JUN., ANDRÉ FÉRON and MICHEL THÉRÈSE GRIVET: The mechanism of the production of cosmic bundles. The experimental results described support the mechanism of production indicated by Bhabha and Heitler for the soft cosmic rays, that is, the group of electrons and photons present in the lower atmosphere.

NICOLAS PERAKIS and LÉANDRE CAPATOS: The thermomagnetic study of the complex compounds $(Ag_2Cd_4(C_6H_5N)_8)_2O_8$.

MAROUS BRUTZOUS: The heat of formation of hydrocarbons.

J. TIMMERHANS and H. BODSON: The surface tension of water and that of heavy water. The variation of the surface tension of water with temperature shows an anomaly at 13° C.; with heavy water this appears at 17° C. This anomaly has not been detected by other workers on this subject.

G. DUCH: The variations of the mechanochemical constants of the benzene hydrocarbons along the vaporization curve with origin at 74.5 cm. mercury.

PAUL BARY and JEAN HERBERT: The transformation points of glasses.

ALBERT TIAN and EDOUARD GAND: The ionic dissociation of the alkyl halides. Experimental evidence that, contrary to the view usually accepted, alcoholic iodides in aqueous solution behave as weak electrolytes.

CARSTEN HOLTHERRMANN and PAUL LAFFITTE: A new oxide of lead. The existence of Pb_7O_{11} has been proved from a study of the composition of the oxide as a function of the temperature under a pressure of 200 atmospheres. The only other oxides indicated on the curve are PbO_2 and the red Pb_3O_4 .

VICTOR AUGER and Mlle. NINA IVANOFF: The molybdenum blues. Amorphous colloidal molybdenum blue. The only molybdenum blue appears to be that described by Guichard with a formula $Mo_3O_{11} \cdot 7H_2O$. This blue is amorphous and colloidal.

MME. NATHALIE DEMASSIEUX and LOUIS ROGER: A complex compound formed by lead iodide and lithium iodide in aqueous solution. This has the constitution $PbI_2LiI \cdot 4H_2O$.

LOUIS HACKSPILL and GEORGES WOLF: The thermal decomposition of the barium carbonates.

MICHEL LESBRE: Some halogen organic derivatives of lead.

ANDRÉ MEYER and HENRI DEUTEL: Salts and complex compounds of 6-methyl- and 8-methyl-4-hydroxyquinolines.

GUSTAVE VAVON and JEAN BOLLE: The condensation of the benzene hydrocarbons with chlormethyl ether. Method of alkylation of aromatic nuclei.

ANDRÉ DEMAY: The role of static and dynamic phenomena in the genesis of the Cristallophyllian.

JAQUES FLANDRIN: The attribution to the Oligocene of a part of the Nummulitic strata of the Kabylie of Djurdjura and its western prolongation (Algiers).

JEAN CUVILLIER: The presence of the marine Carboniferous in the ouadi Abou Darag (Arabian desert).

EDMOND ROTHÉ and MME. ARLETTE HÉE: Prospecting by the penetrating radiations in the trap and granite quarries of Raon-l'Étape.

LOUIS BOUNOURS: The fate of the germinal line in the russet frog after the action of ultra-violet rays on the lower pole of the egg.

TCHOU-SU and CHEN-CHAO-HSI: The spontaneous activation of the egg of the russet frog (*Uraeus muratus*) in contact with fresh water.

MAURICE LEMOIGNE, PIERRE MONGUILLON and ROBERT DESVRAUX: The reduction of nitric acid to hydroxylamine by the higher plants. The role of ascorbic acid. The juice of lilac reduces nitrites to hydroxylamine and under the same experimental

conditions ascorbic acid behaves similarly. Ascorbic acid is always present in the leaves and hence is probably the cause of the reduction of nitrite by the juice.

MICHEL A. MACHEBOEUF, MMES. GHOZZET LÉVY and MARGUERITE FAURE: Researches on the chemical nature of the lipid-fixing haptene of tubercle bacilli. Chemical study of the purified active fraction.

PIERRE LÉPINE, PIERRE MOLLARET and BORIS KREIS: The receptivity of man to the murin virus of lymphocytary choriomeningitis. The experimental reproduction of benign lymphocytary meningitis.

Washington, D.C.

National Academy of Sciences (*Proc.*, 23, 251-294, May 15).

F. ZWICKY: A new cluster of nebulae in Pisces. During September and October last year, more than a hundred photographs with exposures of ten to thirty minutes were obtained at Mount Palomar with the new 18-inch Schmidt telescope of the Carnegie Institution of Washington; characteristic features of the instrument are effective aperture 18 inches, focal ratio $F/2$, diameter of field used about 9.5°, limiting magnitude about 17.5. A large swarm of nebulae in Pisces of large extension and asymmetrical shape suggesting rotation of the whole was observed.

R. A. GORTNER and H. B. BULL: Electro-kinetics. (19) Interfacial energy and the molecular structure of organic compounds. (v) The electric moment of Al_2O_3 : benzene-nitrobenzene interface.

JENNY E. ROSENTHAL and LLOYD MOTZ: Application of a new mathematical method to vibration-rotation interaction.

K. G. SCOTT and S. F. COOK: Effect of radioactive phosphorus upon the blood of growing chicks. Growing White Leghorn chicks were given substantial doses of radioactive phosphorus (prepared by irradiation of red phosphorus) in the form of phosphoric acid. It gave rise to effects not obtained with X-rays. Lymphocytes, which are sensitive to X-radiation, were little affected; polymorphonuclear leucocytes, which are not much affected by X-rays, were much decreased in number. These effects are attributed to deposition of the radioactive phosphorus in the bones, which allows bombardment with radiation of the bone marrow, the source of the polymorphonuclear leucocytes, whereas X-rays only reach the marrow with difficulty.

J. VAN OVERBEEK: Effect of the roots on the production of auxin by the coleoptile. If the root systems of *Avena* seedlings are removed, after 15-20 hours the auxin production is much reduced, causing decreased growth. When both roots and seed are removed, the plants do not 'regenerate' and their curvatures increase steadily. It is suggested that auxin itself and a precursor are present in the seed; the latter is transported independently of the root system, and the former in the transpiration or root-pressure stream.

F. D. MURNAGHAN: The irreducible representations of the symmetric group.

G. A. MILLER: Groups of order less than 2^m having $m-1$ or $m-2$ independent generators.

H. WHITNEY: Products in a complex.

A. GLEYZAL: Linear orders.

C. H. DOWKER: Hopf's theorem for non-compact spaces.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

STRUCTURAL ENGINEERING ASSISTANTS in the Directorate of Fortifications and Works of the War Office—The Under-Secretary of State (C.5), War Office, S.W.1 (August 16).

ASSISTANT LECTURER IN PHARMACY in the Technical College, Bradford—The Principal (August 28).

TECHNICAL OFFICER in the Signals Experimental Establishment, at Woolwich—The Secretary, Royal Engineer and Signals Board, Regent's Park Barracks, Albany Street, N.W.1 (August 27).

LECTURER IN PHYSICAL CHEMISTRY in the Battersea Polytechnic, London, S.W.11—The Principal (September 6).

LECTURER IN PATHOLOGICAL BIOCHEMISTRY in the University of Glasgow—The Secretary of the Court (September 11).

DIRECTOR OF RESEARCH of the Institute of Brewing—The Secretary of the Institute, Brewers' Hall, Addle Street, London, E.C.2 (October 15).

CIVIL ENGINEER in the Public Works Department of the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1.

Milk Supply and National Health

A FEATURE of the present-day interest in nutrition is the number of unofficial organizations which have sprung up with the object, by propaganda and other means, of directing attention to what is naturally and properly considered to be a matter of immediate public concern, and of stimulating the Government to take action on recommendations regarding nutritional needs which have been made by expert committees of the League of Nations, the Ministry of Health and other authoritative bodies.

Active among these organizations is the Children's Minimum Council—a non-party body the aim of which is to secure that no child shall, by reason of the poverty of its parents, be deprived of at least the minimum of food and other requirements necessary for full health. Undeniably, widespread damage is caused to our national health by malnutrition during pregnancy and lactation and in the early years of childhood. Undeniably, also, inadequate family means among a large section of our population is the chief contributory factor to the existence of this state of affairs. Such is proved by the recent surveys of Orr, M'Gonigle, Rowntree and others.

There is much that is still controversial regarding the right nutrition of our people ; but for those who seek an early improvement in existing conditions there is one guiding principle which may be followed without fear of contradiction or misdirection. It is the indisputable value of milk for nursing mothers and children.

In a recent memorandum on "Milk for Mothers and Children under Five", the Children's Minimum Council stresses the case for cheap milk. Expert Government committees have now unanimously declared that the desirable daily amount of milk

for children is from one to two pints, for expectant and nursing mothers about two pints, and for other adult members of the community half a pint. At the present average prices, a family in which there are three children taking, say, one and a half pints a day each, an expectant mother taking two pints, and a father taking half a pint, would have an average milk bill of 13s. 3d. a week. Such an expenditure is, of course, quite beyond the means of working-class families with dependent children.

Consumption of milk in working-class households is far below the amounts regarded as desirable. Statistics from all over the country show how consumption drops with falling income and with an increasing number of children in the household. Many children get little or no fresh milk. For example, a survey of more than thirteen thousand school children in the Glasgow area showed that 57·7 per cent did not drink milk at all.

The proposal of the Children's Minimum Council is that milk should be made available at 1½d. a pint for expectant and nursing mothers and children under school age in families covered by National Health Insurance or of equivalent economic status. Both producers and distributors should be asked to make some concession in their prices for milk supplied under the scheme, and whatever subsidy is thereafter needed to bring the price down to 1½d. a pint should be paid by the national Exchequer. It is estimated that there are in Great Britain about three and a half million expectant and nursing mothers and children under five. The Council argues that a yearly Government subsidy of just over one and a half million pounds would suffice to provide for an annual distribution of eighty million gallons of cheap milk among that number. This is

on the assumption that their orders for the milk would average half a pint per head per day.

Any scheme which attempts to break down the price barrier preventing an adequate consumption of milk by those who most stand in need of it deserves our attention. Nevertheless, however laudable in itself, this new scheme is but another expedient (of which there are already three in existence) to remedy an evil the root cause of which lies much deeper than the mere inability of people to pay for milk. Various State-aided schemes for the provision of cheap milk to mothers and children are already in operation under the Public Health Act of 1936, the Education Act of 1921 and the Milk Act of 1934. Admittedly there are defects and anomalies in these schemes; but another will only bring confusion to an already

complicated position and further increase the administrative difficulties of our already overburdened public health services.

The case requires more drastic handling, and demands a fundamental change in the whole statutory position which at present governs the production and marketing of milk. In the past, the Government has tended to serve the economic interests of producers at the expense of the health interests of consumers. While no one will deny a fair return to the producer, it is out of all proportion that the interests of 175,000 producers should come before those of the ten million children on whose health the future of the country depends. The time has come when the Government must take a comprehensive view, and, without fear or favour, design a unified milk policy to meet the needs of the whole community.

Genetics and Plant Breeding in the U.S.S.R.

THE fourth session of the Lenin Academy of Agricultural Sciences, held in Moscow at the end of 1936, witnessed a determined campaign against genetics as the main basis of scientific plant breeding¹. It is only now, however, that detailed reports of some of the speeches made at the session are available, while further light is thrown upon the controversy by recent Soviet publications.

The attack was opened by a group of plant-breeding experts headed by T. D. Lysenko, a member of the Odessa Institute for Selection and Genetics. The main ideas of Lysenko do not appear to have been published in a scientific form, but they are expressed in a popular pamphlet² and in his speech at the session of the Academy of Agricultural Sciences³. They are based on no lesser, and no later, authority than that of Charles Darwin, whose teachings according to Lysenko "were unable to blossom out properly in bourgeois countries. The best Darwinists in capitalist countries, as for example Burbank in America, as well as our revolutionaries-biologists K. A. Timiriazev and I. V. Michurin in the Czar's Russia, were lone fighters." The works and theories of de Vries, Johannsen, Bateson, Morgan, are dismissed on the strength of a few quotations from their writings, suggesting their critical attitude to some of Darwin's ideas, all of which are held by Lysenko to be the last word in biology.

The actual controversy is centred around two points of practical plant breeding. One concerns the problem of crossing and selection of self-fertilizing pure line plants. According to Lysenko, pure lines if cultivated for a long time are liable to degeneration. This can be prevented, and the line even improved, by artificial cross-fertilization within the variety. "Small field experiments" made at Odessa with some varieties of wheat have shown an increase in the yield from cross-fertilized seeds, and this was taken to be sufficient to consider the method ready for immediate introduction into practice. About 10,000 farmers on 2,000 collective farms were instructed to sterilize wheat plants by cutting stamens to prevent self-fertilization. As a result, 500-1,000 gm. of cross-fertilized seeds were obtained on each farm. "If it happens that the seeds from intra-varietal crossing should be of higher quality, should produce plants with greater yield . . . , there will be no obstacle to a rapid transformation of a kilogram of seeds on each farm into tens of tons". Since Lysenko is also practically certain (although without apparent data) that the improved plants will be more resistant to winter frosts, he urged the Academy to pay serious attention to the question of the immediate necessity of introducing the method of cross-fertilization on "at least 50-70 thousands of collective farms".

It does not appear to be safe to criticize such enthusiastic plans, containing a promise of enormous and immediate progress towards the fulfilment of Stalin's recent order for increased agricultural production. N. I. Vavilov¹, in his reply to Lysenko, merely pointed out that many pure varieties of wheat, barley, etc., have existed without any "degeneration" for centuries, and there is no need to seek to improve them by intra-varietal cross-fertilization. Even if such crossing should produce an improvement (due to heterosis), it remains to be shown that the improvement will be lasting, since usually heterosis disappears in a few generations. G. Meister², who summed up the discussion, very cautiously suggested that it would be premature to develop extensive practical programmes while the method is still being studied experimentally.

While this first point of the discussion was mainly concerned with a practical problem, the second presented a clash between two almost diametrically opposed fundamental conceptions of biology. The discussion developed round Lysenko's forceful statements that the external conditions under which a plant develops have a profound effect not only on the somatic, but also on the sex cells. Therefore, responses of the constitution of an individual plant to its environmental conditions are inheritable, contrary to the views of "bourgeois" geneticists. This theory is based on three incomplete years of experiments with the vernalization of winter wheat and rye; none of these experiments was carried beyond the fourth generation and the results do not appear fully conclusive³. Nevertheless, Lysenko claims that the possibility of "changing the nature of plants" has been definitely proved, and promises in the near future to develop new varieties of winter wheat with increased cold-hardiness, of cotton requiring less heat for its growth, etc.

On the face of it, Lysenko's theory is nothing but Lamarckism in its simplest form, and this was pointed out by several speakers. Such accusations of being unfaithful to Darwinism appear, under Soviet conditions, to be tantamount to charges of high treason. Lysenko, therefore, had to insist that his theory is nothing but a development of most orthodox Darwinian views. His defence is worth quoting, since it provides a typical example of methods of discussion adopted by some Soviet scientific investigators: ". . . no work can possibly produce positive results if it starts on the

basis of Lamarckism. If, by suitable breeding of plants, we have already succeeded in altering their hereditary nature in the desired direction, this alone proved that we are not Lamarckists. . . ." Lysenko insists further that he is not against the science of genetics, but "genetics as one of the most important sections of agro-biological science must be . . . remade in our Soviet way, without accepting many anti-Darwinian tendencies of fundamental genetic conceptions".

The problem of the inheritance of acquired characters has such an extensive literature and is still so far from its solution, that recent Russian work on vernalization and allied phenomena should be regarded merely as providing additional experimental data on the subject. Some of the results may be suggestive, but they certainly do not in any way justify Lysenko's assertions that the secret of "changing the nature of plants" is now discovered. These assertions would not be worth recording, were it not for the fact that they led, not to a healthy discussion, but to unscrupulous attacks on the large Russian school of geneticists deservedly appreciated by biologists in other countries. It is true that Lysenko and his colleagues veiled their attacks, for example, on Vavilov, by professing profound respect for his work; but at the same time they lost no opportunity for stressing what they consider to be anti-Darwinian tendencies in his ideas. In a country where Darwinism—as interpreted by Engels and Lenin—constitutes the ideological basis of official philosophy, arguments of this kind savour of denouncing an enemy of the State. Some practical effects of these accusations were pointed out by Meister⁴, who said that certain Soviet editors already refuse to publish articles dealing with genetics, which appear to them bordering on counter-revolution. It is also perhaps not a mere coincidence that the International Genetical Congress, which should have been held in Moscow this summer, has been postponed.

On the whole, the discussions, which must have stirred very deeply all biological workers in the Soviet Union, appear to be of very limited theoretical interest. They are, however, of outstanding significance in revealing the atmosphere in which scientific investigators in totalitarian countries have to live and work.

Willard Gibbs and his Work

A Commentary on the Scientific Writings of J. Willard Gibbs, Ph.D., LL.D., formerly Professor of Mathematical Physics in Yale University.

Vol. I: Thermodynamics; dealing with the Contents of Volume One of the Collected Works. Edited by Prof. F. G. Donnan and Prof. Arthur Haas. Pp. xxiii+742. Vol. 2: Theoretical Physics; dealing with the Contents of Volume Two of the Collected Works. Edited by Prof. Arthur Haas. Pp. xx+605. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1936.) 45s. net.

IT is now sixty-four years since Willard Gibbs published in the *Transactions of the Connecticut Academy* the first of his classical papers on thermodynamic theory, and thirty-five since the publication of his "Elementary Principles in Statistical Mechanics".

Almost contemporaneous with the last-mentioned event was the introduction by Planck of the 'quantum of action', which was destined to revolutionize atomic and molecular physics. It is not inappropriate, now that the new theories have largely taken shape, that Gibbs's work should be rediscussed with the view of examining how much of it retains its validity in the light of modern physics.

The two volumes under review have been prepared under the auspices of Yale University, where Willard Gibbs was professor. They consist of a symposium, to which a number of distinguished workers have contributed, with the double object, first of doing honour to the memory of Willard Gibbs, secondly of providing a commentary to guide the reader of his collected works. This last indeed is very necessary, for Gibbs's own treatment is frequently far from easy to follow and, apart from this, both nomenclature and methods differ appreciably from modern practice.

In view of the above intention, Gibbs's notation has been adhered to, and the commentary begins with a very brief but very valuable note on symbols and nomenclature by Prof. F. G. Donnan, for which anyone who has lost himself in the maze of 'free energies', 'available energies' and 'thermodynamic potentials', as envisaged by various authors, will be indeed thankful.

The first volume, which is under the general editorship of Prof. Donnan and Prof. Arthur Haas, deals with the subject-matter of vol. 1 of Gibbs's Collected Works, that is, mainly with his first three classical papers.

The general theory of thermodynamics as expounded by Gibbs forms the theme of quite a number of the contributions, in particular articles (D) "The General Thermodynamic System of Gibbs", by J. A. V. Butler, (G) "The Phase Rule and Heterogeneous Equilibrium" by G. W. Morey, and (J) "The Fundamental Equations of Ideal Gases and Gas Mixtures" by F. G. Keyes. Prof. E. A. Milne contributes an article on the thermodynamic functions and criteria of equilibrium, and Prof. Schreinemakers one on graphical methods using the free energy function. To the same group belongs the leading article (N) of the second volume, "The Thermodynamic Principles as Extended and Perfected by Gibbs" by Prof. Arthur Haas.

Special subjects such as osmotic equilibrium (E. A. Guggenheim), the thermodynamics of elasticity and interface phenomena and capillarity (James Rice) are dealt with in separate articles.

There is naturally a good deal of overlap; thus Gibbs's paradox in connexion with the diffusion of two gases into one another is described and discussed by both Dr. Butler and Prof. Haas, and this is not an isolated case. On the whole, this overlapping is rather an advantage than otherwise; the differences of presentation are often complementary and illuminating.

It is, however, to be regretted that, although Gibbs's famous criteria for equilibrium are explained at least three times, namely, by Butler and by Milne in vol. 1 and by Haas in vol. 2, there appears to be nowhere an adequate discussion of their validity, at any rate in the most difficult case, that of unstable equilibrium. Butler alone attempts to deal with this case, and he follows Gibbs's own lines; but unfortunately Gibbs is here entirely unconvincing. In view of the importance of these criteria a careful and critical examination would not have been out of place.

The second volume, which deals nominally with vol. 2 of the Collected Works, contains two articles, (N) and (O), devoted to classical thermodynamics. The first has already been mentioned above. The other, by Prof. Epstein, deals with the subsequent continuation by Nernst and others of Gibbs's purely thermodynamical work.

Other articles by Leigh Page, E. B. Wilson and Arthur Haas concern Gibbs's contributions to the theory of light, to vector analysis and multiple algebra and to dynamics respectively.

The bulk of this volume is devoted to Gibbs's work on statistical mechanics, most of it being from the pen of Prof. Haas; but the last two

articles but one, by Epstein, contain a very instructive criticism and appreciation of Gibbs's work in the light of recent theories. Haas himself, at the end of article (R), has dealt with the derivation of the ideas of wave-mechanics from Gibbs's conception of phase-space, and the whole of this section is highly suggestive and deserves the most attentive reading.

Admirable as the "commentary" is in general, one cannot help feeling occasionally that it is itself at times in need of a commentator to clear away obscurities.

This is noticeable, for example, in the treatment of elastic solids in vol. 1 (art. K), which is far more difficult to follow than the usual expositions of the analysis of stress and strain in treatises on elastic theory. In one place (p. 445) the writer of the article uses as "more convenient" a set of strain-variables which do not form a tensor and which, for that reason, would be highly inconvenient for use in an isotropic solid.

Another example may be taken from vol. 2, pp. 192-203, where a number of difficulties occur. Thus (a) on p. 192, the reader is not told why

the vanishing of $\int Dv_n df$ must involve $\frac{\partial D}{\partial t} = 0$;

(b) on pp. 196-97, the vital assumption by Gibbs of the form $\exp \{(\psi - \epsilon)/\theta\}$ for P is described as "plausible"; but there are an infinity of forms for P which will ensure the convergence of the integral $\int \dots \int P dq_1 \dots dp_n$, and the reader might well expect to be told why one "plausible" form is preferred above all others; (c) on p. 198, the statement that $\int \dots \int dq_1 \dots dq_n = f(V)$ is not true unless the q 's are Cartesian co-ordinates, in which case f can only be a power, as correctly stated on p. 200; (d) on p. 202, no explanation is given of the absence of a term in $d\theta$ in equations (56) and (60), although ϵ as defined by (55) appears to be a function of θ .

Taken as a whole, however, the commentary forms a most welcome addition to the literature of a difficult subject, and will be not only a worthy monument to one of the greatest mathematical physicists of the nineteenth century but also an excellent exposition of his ideas by some of the greatest experts in the subject at the present time. The work involved has clearly been enormous, and the editors and their collaborators have well deserved the congratulations which they undoubtedly will receive.

It is perhaps still too early, in the present fluid condition of physical science, to estimate Willard Gibbs's position in the development of theoretical physics and chemistry. Those who hope for such an estimate from these two volumes are likely to be disappointed. We are given a very full and very instructive paraphrase of Gibbs's work, and deductions from it. We are shown its connexions with contemporary and subsequent developments; but no real attempt is made to apply critical analysis to the work itself and to discriminate between the best and (at any rate) the second-best. Yet that in such a mass of new methods and results weaknesses or indeed failures must have occurred seems inevitable; even Newton was not exempt. A commentary written in a more critical spirit would certainly have done Gibbs's memory no harm and would undoubtedly have helped towards a better understanding of his work.

Even on the question of the relative value and permanence of the thermodynamics and the statistical mechanics—which represent widely different scientific philosophies—we are left in doubt. Possibly this is the unavoidable result of the symposium method, and of a natural diffidence on the part of individual contributors. But the reader puts down the book with the feeling that the final summing-up about Gibbs has yet to be written.

L. N. G. F.

The Peasant Farmers of Ireland

The Irish Countryman:

an Anthropological Study. By Dr. Conrad M. Arensberg. Pp. xi+216. (London: Macmillan and Co., Ltd., 1937.) 10s. 6d. net.

DR. ARENSBERG'S anthropological study of the peasant-farmer population of western Ireland will be held to confirm their views by those who believe that much of the primitive survives in the modern Irishman. It is this element in his make-up, they would maintain,

which has persisted, certainly from pre-conquest, and possibly from prehistoric, days, and lies at the root of a misunderstanding between governors and governed, dating back so far as the twelfth century and distorting, as it would appear to the Irish, the vision of Giraldus Cambrensis.

As a social anthropologist, Dr. Arensberg's approach to the culture of the west is that of the analyst of patterns of behaviour. He shows how the whole social nexus of the peasant-farmer class, with which he is dealing, nucleates in the land,

that is, in the farm holding, not merely as a matter of the internal economy of a single unitary organization, but also as one among a number of similar organizations, with mutual accommodations, perhaps even obligations, in co-operation at times of pressure in their agricultural functions, and a conditioned relation to the traders of the nearest or central town. The all-pervading influence of the land, and the character of the social economy to which it gives rise, can be discerned most clearly, perhaps, in such diverse matters as the system of passing the control of the farm to one of the sons at the oncoming of age—though not necessarily of senility—match-making, the late age for marriage, and the system of retail purchase and credit, which are not a question of finance simply, but depend on kinship, social relation, or other economically extraneous considerations, rather than price and quality.

It is interesting to translate Dr. Arensberg's study of patterns and nuclei of behaviour into the more formal and familiar terminology of traditional methods of observation. The primitive character of this community, with which he is

concerned, immediately becomes more clearly apparent. It is then evident that in the peasant-farmer population we are dealing with a community in which the unit is the family, supplemented by the extended family and the kinship organization. It has its age classes, each with its club-house, and headed by an assembly of elders, who regulate the affairs of the community and are the repository of tradition. Marriage follows on or accompanies initiation into manhood, which goes with the accession of responsibility on the farm. Hence the late age of marriage. It follows also from this peculiar economy that the town is literally the market town, a meeting place for the exchange of produce, which functionally has no independent existence. There is also a place for primitive religious belief, as over and above the orthodox creed, there is an all-pervading animism, the belief in "they", the fairies, or *sidhe*.

It is perhaps not remarkable that a mentality in which these elements of behaviour are so deeply engrained as to have survived for centuries should have been incompatible with a system of landlordism.

Chemistry for Everyman

Chemistry, Matter and Life

By Dr. Stephen Miall and Laurence Mackenzie Miall. Pp. x+296+8 plates. (London: Edward Arnold and Co., 1937.) 7s. 6d. net.

THE popularization of chemical science is a notable feature of the twentieth century, and the appearance of the volume under consideration is welcome evidence that the demand for books which give a readable and accurate account of the achievements of scientific chemists still continues. In looking back over the past thirty years or so, it is of interest to note how the methods have altered by which authors have sought to capture the interest of their readers. Formerly, it seems to have been considered necessary to emphasize in the titles chosen the wonder, the romance or the mystery of chemistry, and in the text the reader was constantly being aroused to amazement and wonder. Each sentence, almost, ended in an exclamation mark, and it was sought to hold the attention of the reader by means of slogans and the devices of the advertising agent.

Nowadays, these methods of exposition have fortunately almost disappeared, and the intelligent and educated public is now supplied with books, such as the one before us, in which the facts and

theories of chemistry are presented clearly and soberly and left to make their own impression. One cannot but welcome the present work, in which the authors "have tried to describe in language that any educated person can understand some of the main principles of chemistry, the nature of matter, and some of the chemical changes that take place in living plants and animals". The qualifications of the senior author, at least, are a sufficient guarantee that the attempt has not been made in vain.

Within the compass of less than three hundred pages, and in a succession of twenty-seven chapters, the authors have considered briefly, sometimes too briefly, the general aspects of much of present-day chemistry. In the first eighteen chapters we have presented to us an account of modern views regarding the constitution of matter of the arrangement of atoms and molecules in crystals, of the spontaneous transformations which atoms are undergoing in radioactive substances and of the similar transmutations which can now be brought about artificially. The discussion of these and other topics leads on to the consideration of some of the substances which are formed in the bodies of plants and animals and of the chemical processes which take place in the living

organism. These closing chapters are necessarily less easy to read and understand than the earlier ones, yet the authors have succeeded in giving to the general reader an idea of the truly extraordinary work which has been achieved by chemists in unravelling the molecular constitution of the complex compounds which build up the structure of plants and animals, which control the health of the animal organism and which give to plants their marvellous colours.

The book can be recommended to all who wish to obtain some knowledge of what the science of chemistry means. It is readable and reliable, and is well illustrated by diagrams and plates; but why, one may ask, should there be given on the jacket a picture of an alchemist in his laboratory rather than a picture of, say, Ramsay or of Robinson? Is it thought that the fading glamour of alchemy, of which there is no mention in the text, may act as a lure?

ALAN. FINDLAY.

Technological History

The Collected Papers of Rhys Jenkins, M.I.Mech.E.

comprising Articles in the Professional and Technical Press mainly prior to 1920 and a Catalogue of other Published Work. (Links in the History of Engineering and Technology from Tudor Times.) Pp. x+247+8 plates. (London: Newcomen Society, 1936.) 21s.

TWO things strike one at the first glance into this handsome volume: first, the wide range of Mr. Jenkins's researches and his large output; secondly, the reflected glory which shines on the Newcomen Society through having published the volume, apart from the fact that it is "a token of the affectionate regard in which he is held by members of the Society".

Closer examination of the work reveals that it is nearly all based on hitherto unpublished material obtained from the most out-of-the-way sources, indicative not only of keen research, but also of a flair for knowing where to look. Not only so, but also Mr. Jenkins has visited the localities where the industries he describes have been carried out; he has in some cases located their sites and he has exhausted the traditional sources of information locally. What is so refreshing about the author is that he brings to the sifting of the evidence and the weighing of facts a critical inquirer's mind. He examines the stories which have hitherto served as history, and extracts from them whatever modicum of truth they may contain. His papers may be studied as models of historical research, and he himself is rightly regarded as the doyen of students in the field of engineering and industrial history.

The papers have been gathered from many sources, but are reprinted substantially as they appeared; where new matter has come to light after the publication of any particular paper, this matter has been dealt with by Mr. Jenkins in an appendix.

In general, the papers represent Mr. Jenkins's activities prior to the founding of the Newcomen Society by himself and others in 1920; since that date, most of his contributions have found their way into the *Transactions* of that Society. Taken together, they thus form a corpus of all his work up to date.

Turning to the subject-matter in detail, it may be conveniently classified under these headings: mechanical technology; steam engineering and foundry work; hydraulic and sanitary engineering; industrial and economic history. In the space at disposal, attention may be directed to a few of the papers. Foremost among them are those which elucidate the history of the steam engine and the work of Sir Samuel Morland, Thomas Savery, Thomas Newcomen and Henry Beighton. It may be said without hesitation that Mr. Jenkins's researches in this direction have added more to our knowledge than the whole of that available previous to his time. Another subject treated in a masterly manner is the history of paper-making in England in 1495-1788; even the site of the mill of John Tate, the first English paper maker, had been lost. The history of an industry—that of tin-plates—that has been associated with Mr. Jenkins's native county—is the subject of what will undoubtedly remain a classic memoir.

Sufficient perhaps has been said to indicate the interest of these "Collected Papers". To conclude the volume there are complete lists of the published works of Mr. Jenkins, authorities quoted, and a really good index. This is, we believe, the first time that such a volume has been published by an engineering society in Great Britain, and the Society, the editor, Mr. E. W. Hulme, and the printers are to be congratulated on the results of their combined efforts. No student of industrial history can afford to overlook this remarkable volume.

Vitamins in Theory and Practice

By Dr. Leslie H. Harris. Pp. xix+242. (Cambridge: At the University Press, 1937.) 8s. 6d. net.

THE first edition of Dr. Harris's book was published at the end of 1935 and reviewed in *NATURE* in the spring of 1936 (137, 868). Its deserved success is doubtless one reason why a new edition has been needed so soon; another is the speed with which advances in vitamin chemistry have been made during the last eighteen months, a speed unusual even in this exceptionally fast-moving branch of biochemistry.

During that period the exact structures of aneurin chloride (vitamin B₁) and of lactoflavin (part of the 'vitamin B₂ complex') have been made known, and both have been completely synthesized. The detailed structures of two antirachitic vitamins, calciferol (vitamin D₂) and the 'natural' vitamin of halibut and tunny liver oils (vitamin D₃) have been worked out and a generally accepted formula has been proposed for each; the latter has been prepared from inactive substances, both 'natural' and of laboratory origin, and it has also been obtained crystalline, though too recently for the fact to be recorded by Dr. Harris. The claim by Evans to have isolated vitamin E, which he calls "tocopherol", is accepted by Dr. Harris, but he would not find that all workers in this field agree with him on the matter.

Apart from expanding his book to include these items of new discovery, the author has made few additions. He might, perhaps, with advantage have included reference to the more recent work on the treatment of habitual abortion with wheat-germ oil or extracts made from it (Shute, Watson, Currie), especially as this work confirms the original observations of Vogt-Möller, recorded in this edition in words identical with those used in the first. But Dr. Harris is perhaps wise in a book of this nature, intended for lay consumption, to err on the side of caution.

A. L. BACHARACH.

Thirty Years of Nature Photography:

a Personal Record of Two Observers. By Seton Gordon. Pp. xi+100+108. (London, New York, Toronto and Melbourne: Cassell and Co., Ltd., 1936.) 21s. net.

THE author has been photographing birds and their nests since 1903, inspired originally by the books of Richard Kearton. His wife had also observed and photographed sea and moorland birds, and after marriage the two enthusiasts helped each other in this fascinating pursuit. The beautiful plates of this book are the result of their collaboration, the letter-press explaining the methods used, with particular emphasis on the necessity for a 'hide', and for two observers to use it.

There are photographs of sea birds, moorland birds, a few of seal and deer, and two remarkable pictures of crested tits. The account of the taking of these photographs shows that considerable physical fortitude, besides infinite skill and patience, went to the making of a book which admits the reader to the intimate family life of these untamed creatures.

Most of the photography was done with a large camera from a hide, a hand camera being used for sea birds only. The photography of the latter is comparatively simple as they are not very shy, the main difficulty being the inaccessibility of their haunts. But photographs such as those of the golden eagles caressing each other above their eaglet, feeding and sheltering the eaglet, and of the hooded crow with her nestling are wonderful achievements, alike in photographic skill and bird study. Regarded pictorially, the 'close-ups' are better than such pictures as "Stags Crossing a River", where the lens is too good for the picture, the deep focus giving no sense of recession.

The author comments on the difficulties found in enforcing the Wild Birds Protection Act. Books such as this must, we hope, turn a reader's thoughts to study of a bird as a lovely sentient being, rather than as a stuffed corpse or a blown egg.

Flora of Jamaica:

containing Descriptions of the Flowering Plants known from the Island. By William Fawcett and Dr. Alfred Barton Rendle. Vol. 7: Dicotyledons—Families Rubiaceae to Compositae. By the late Spencer Le Marchant Moore and A. B. Rendle. Pp. ix+303. (London: British Museum (Natural History), 1936.) 15s.

THE continuation of this valuable work is very welcome, and we note with pleasure that there is every hope of its speedy completion. The present volume is filled almost entirely by the accounts of the Rubiaceae and Compositae, which were prepared by the late Mr. Spencer Moore and have been completed by Dr A. B. Rendle. The latter author has also worked out the Campanulaceae, and has successfully unravelled the difficulties which obscured the identity of some of the ten species of *Lobelia* occurring in Jamaica. All students of tropical American plants will be grateful for the attention to nomenclature and synonymy, the care in examining historic types, and the general finish which have from the first been marks of this distinguished production.

Einführung in die Vektor- und Tensor-rechnung: unter besonderer Berücksichtigung ihrer physikalischen Bedeutung. Von Prof. Dr. Harry Schmidt. Pp. vi+126. (Leipzig: Max Jänecke, 1935.) 5.80 gold marks.

THIS is an excellent account of vector analysis, starting at the beginning, based on sound mathematical principles, and clearly explained. The vector theorems are well illustrated by hydrodynamical applications; the tensor of the second order (the work is carried no further) is exemplified by the theory of elasticity. The author believes that an exact treatment need not be more difficult, and is certainly easier to understand, than a popular exposition lacking in rigour and based on intuition. With this we entirely agree, and can recommend this book to all who wish to learn vector methods and their application.

The Search for the Isotopes of Hydrogen and Helium of Mass 3

By The Right Hon. Lord Rutherford, O.M., F.R.S.

AFTER the discovery by Urey of the isotope of hydrogen of mass 2 (deuterium) and its concentration by electrolysis, it was natural to examine whether any other stable isotopes of hydrogen, and particularly ^3H (tritium, symbol T), are present in ordinary hydrogen. In this article an account will be given of the chequered history of the many investigations to throw light on this question, and incidentally also of attempts made to detect the presence of the helium isotope of mass 3, which is believed to be produced in certain transmutations.

It was natural to suppose that the concentration of deuterium by electrolysis of water should lead also to a concentration of tritium to a considerable extent. Using a direct spectroscopic method, Lewis and Spedding¹ in 1933 looked for the presence of a spectrum line corresponding to ^3H in hydrogen released from a rich sample of heavy water, but with negative results. They concluded that if tritium were present at all its concentration was less than 1 in 6×10^4 , compared with ordinary hydrogen.

Experiments with a similar object were carried out in Princeton University in 1934 by Lozier, Smith and Bleakney². A sensitive form of mass-spectrograph designed and operated by Bleakney was used to detect the presence of charged molecules TD of mass 5. They estimated that the concentration of T was about 5 in 10^4 after the initial volume of ordinary water had been reduced to 1 part in 225,000. The experiments were continued by Prof. H. S. Taylor and his collaborators³ until the volume was reduced to 1 part in 150 million. In these experiments about 75 tons of ordinary water were electrolysed down to 0.5 c.c. The concentration of T/D using Bleakney's method was found to be about 1 in 10^4 , and they concluded that the abundance of T in ordinary water was about 7 in 10^{11} .

In the meantime Oliphant and Harteck⁴ in Cambridge had found definite evidence that the bombardment of a deuterium preparation by fast deuterons led to two types of transformation, in one of which an isotope of hydrogen of mass 3 was liberated, and in the other an isotope of helium of mass 3. From the energies released in these reactions, it was deduced that the masses of these two isotopes are nearly the same, namely, 3.0171 when the mass of a hydrogen atom is taken as 1.0081. The general evidence suggests that

both these new isotopes are stable under normal conditions.

It was clear that it was matter of much scientific importance to obtain sufficient quantities of these new isotopes not only to determine their masses with precision but also to investigate the interesting transformations which might be expected to occur when the ions of these isotopes were used for bombarding purposes. An account will be given later of attempts to obtain detectable quantities of these gases by direct transmutation, but I will first deal with experiments to obtain detectable quantities of tritium by continued electrolysis of heavy water. Before the completion of the Princeton experiments, the feasibility of large-scale electrolysis was discussed by Prof. Urey with Prof. Tronstad and Engineer J. Brun of the Norsk Hydro-Elektrisk Kvoelstofaktieselskab of Oslo, Norway, which was producing heavy water in quantity by the electrolytic method. The most suitable methods to employ for the concentration of tritium were discussed by Dr. Farkas and Dr. Oliphant of Cambridge with the representatives of the Norwegian company, which very kindly agreed to carry out the elaborate research programme required. A brief statement of the methods employed, given by the Company, is as follows:

"If ordinary heavy water containing a small quantity of tritium oxide is electrolysed to a small volume, it is to be expected that, in all probability, it will become rich in T_2O . The object of the experiments was to try to accomplish this by electrolytic means.

"The basis used was 43.4 kilos of heavy water produced electrolytically and having an average D_2O content of 99.2 per cent. During the course of nine months and a half, this heavy water was electrolysed to a volume of 11 c.c.

"The electrolysis was carried out under conditions that ought to be considered favourable for the concentration of any tritium oxide that might happen to be present in the heavy water. During the first part of the electrolysis nickel cells provided with iron cathodes were used, but during the last part of the process glass cells with electrodes made of platinum were employed. The cells were constructed in such a manner that there was excellent communication between the anolyte and catholyte. In addition to this, provision was made for efficient reflux condensation of the water

vapour, so as to ensure the purity of the gases developed by the electrolysis.

"The electrolyte used consisted of heavy potassium hydroxide—KOD. In order that the concentration of the electrolyte should not increase too much during the electrolysis, the potassium hydroxide was gradually eliminated from the electrolyte by distilling off the water. The D₂O content of the dry potassium hydroxide obtained by this process was regenerated by being first treated with dry CO₂, the water liberated thereby being then distilled and passed back to the cell.

"The density of the cathodic current during the electrolysis varied from 0.2–0.4 amp./cm.². The temperature of the electrolyte varied from 30° to 50° C.

"After the electrolysis had been completed, the contents of the cells were treated with dry CO₂ (for the purpose of converting the potash into carbonate), and the heavy water was distilled off. No further purification was effected."

Part of this concentrated material was handed to Dr. F. W. Aston to examine in his precision mass-spectrograph whether any tritium was present. The following statement of the behaviour of this material has been given to me by Dr. Aston:

"The vapour of the concentrated heavy water was allowed to pass continually through the discharge tube which was in a very favourable state, the diatomic molecular lines being about 1,000 times as bright as the triatomic. The line 5 was examined by a 40 minutes exposure and the limits of detection estimated by very short exposure of line 4 (D₂) down to 1 second. Line 5 was unquestionably D₂H and no trace of a companion in the position expected for DT could be detected. This would have been about 0.5 mm. away and easily resolved. A second test was made with an exposure of 50 minutes with the same result. As line 4 could have been detected with an exposure of 1/20 second, it follows that

$$\frac{DT}{D_2} < \frac{1}{50,000}$$

The conclusion of Dr. Aston, that no trace of tritium could be found in the concentrated sample by his very direct and simple method, is very disappointing after the time and labour spent in Norway in preparing this material. While it is, of course, difficult to make any certain comparison of the concentration of T to be expected in these two large-scale experiments, it does not seem likely that the concentration of T would be less in the Norwegian experiment. I am informed by the Norwegian company that, in all, 13,000 tons of ordinary water were used for the production of the 43.4 kilos of heavy water employed by them to concentrate the tritium, while Taylor

and his collaborators started with 75 tons. The rather low yield of heavy water in the Norwegian experiments was due to the fact that the cells used were ordinary technical electrolyzers for the production of hydrogen and oxygen, heavy water being regarded as a by-product. In any case it is to be expected that in the earlier stages of the electrolysis the tritium would be enriched at least as much as the deuterium.

There is thus rather a conflict of evidence with regard to the concentration of tritium in the two similar experiments. The American observers obtained a positive result indicating a value of T/D = 1/10⁴ in their enriched sample, while Aston by a more direct method could detect no tritium at all in the Norwegian preparation, and concludes that T/D must be less than 2 in 10⁴. Unfortunately, an intercomparison of the samples is not possible, for Prof. H. S. Taylor informs me that their enriched sample has been lost. It is hoped, however, that it will be possible to arrange to test the Cambridge sample in Princeton by the sensitive method devised by Bleakney. It is important to decide that the ions of mass 5 shown by this apparatus are in fact due to molecular ions TD.

It was felt desirable, however, to confirm the negative result found by Aston by a transmutation test. This is in some cases a delicate method of analysis, as is shown by the fact that the presence of the small amount of deuterium in ordinary water can readily be observed by its use. Experiments were consequently made by Kempton and Miss Maasdorp in Cambridge, to test whether hydrogen separated from this concentrated material showed any characteristic difference from ordinary deuterium, when the accelerated ions were used for bombarding purposes. The ion beam was analysed by a magnetic field, and the part of mass 3, no doubt mainly due to charged DH molecules, was allowed to fall on a target consisting of a deuterium compound. The intensity of the beam of mass 3 was very small compared with that observed for the D ions. From general considerations, we might expect the following reactions to occur for fast ions corresponding to ³H and ³He:

the energy released in each case being about 20 million volts. Owing to the copious production of neutrons from the ordinary D—D reaction, it is not possible to distinguish the small number of neutrons or protons to be expected from the above reactions. On the other hand, the α -particles arising from these reactions should have a range in air of 2–3 cm., and should be readily distinguished from protons, owing to their greater ionizing power. Careful search failed to reveal any

such α -particles, and the number must have been less than 1/5,000 of the protons arising from the D—D reaction. Assuming that these reactions are all equally efficient at the voltage used, it follows that

$$T/D < 1/5,000.$$

While the limit of detection of T by this method is 10 times lower than that deduced by Aston, this conclusion nevertheless affords a useful check in indicating that very little if any T can be present.

It is desirable to add a short statement of attempts made to detect the artificial production of ^3H and ^3He in the D—D reaction already referred to. Since these transformations are highly efficient, and take place for very low bombarding energies, it is to be expected that both ^3H and ^3He should accumulate when an ordinary glow discharge is passed through heavy hydrogen. Accordingly experiments were carried out in America and in Cambridge to produce these new isotopes by passing heavy hydrogen slowly through a discharge tube across which a potential of 60–70 kilovolts was applied. Samples of the gas obtained by this treatment were tested in America for the presence of ^3H and ^3He by the sensitive method of Bleakney, previously mentioned. At first, evidence⁴ of small traces of these gases was found, but we understand that later work has failed to confirm these conclusions.

In the Cambridge experiments made by Oliphant, the treated gas mixed with an excess of helium was passed through the discharge tube, which produced a beam of fast ions for experiments on transmutation. After acceleration, the beam of ions was analysed by passage through a magnetic field, and the ion beam of mass 3 was found to be very feeble compared with that of mass 2, owing to the presence of helium, which has the property of dissociating the charged molecules produced by the discharge. The method of detection of ^3H and ^3He was similar to that already described. A search was made for α -particles which might

be expected to arise from the reactions (1), when the ions of mass 3 fall on a target containing deuterium. No such α -particles were detected, and the number was certainly less than 1/20,000 of the protons liberated from the deuteron beam under the same conditions. Assuming as before that these transformations are all of equal efficiency, it is evident that ^3H and ^3He cannot be present to the extent of 1/20,000 in the deuterium gas.

Attempts have been made by G. P. Thomson and F. A. Paneth in London to produce ^3He by the D—D reaction in sufficient quantity to be detected by the extremely sensitive micro-methods developed by Paneth, but so far without success. It may be that the reaction of ^3H and ^3He with D takes place very easily, so that a stage is soon reached when these isotopes are destroyed in the discharge as fast as they are produced.

The rapid disappearance of ^3H and ^3He by transmutation would account for the very small abundance of these isotopes in the earth and presumably in the sun. A number of experiments have been made to detect the helium isotope of mass 3 in ordinary helium by direct spectroscopic methods, but with entirely negative results. This, however, is not surprising when we consider that terrestrial helium is probably derived from the α -particles of mass 4 expelled from the radioactive substances present on our earth.

It is a striking fact that while in transmutation experiments using counting methods the D—D reaction is on a marked scale, giving rise to very large numbers of ^3H and ^3He particles, yet it does not seem feasible at the moment to obtain sufficient quantities of these two interesting isotopes to study their properties by ordinary physical chemical methods.

Social and Political Application of Nutritional Science

THE historical development of any science is twofold. First come the discoveries of natural principles and facts of theoretical interest. These are followed at varying intervals of time by their application to practical life. The history of nutritional science offers no exception to this rule.

Recently, the trend of nutritional investigation has undergone a marked change. While disinterested studies of a purely theoretical nature

will always bulk large in the pages of scientific journals, there is clear evidence that pride of place is now being given to researches which will hasten the practical application of the new nutritional teaching. In short, there are welcome signs of a lessening gap in the relations between those who are engaged in ascertaining the facts of nutrition and those whose duty is the application of that knowledge to the practical affairs of public health.

Some evidence of this will be found in the fact that the number of papers noted in the section of *Nutrition Abstracts and Reviews* (published by the Imperial Bureau of Animal Nutrition, Rowett Research Institute, Aberdeen), devoted to the application of nutrition to human health has increased by more than 90 per cent in the last five years.

The two outstanding features of present-day investigations are first, the attention which is being paid to the determination of nutritional needs, and secondly, the ascertainment of the extent of means to supply these needs. The economic blizzard which struck the world in the years around 1931 gave tremendous stimulus to this type of study, and we find the world's literature during the years of depression abounding in papers dealing with the influence of the economic crisis on the nutritional needs and health of the people, the dietary resources of the unemployed in relation to their physical fitness, and the prevalence of malnutrition in children and young persons living under conditions of limited means in distressed areas.

The relation between poverty and national physique has been re-examined in the light of our new knowledge of nutritional needs. Many recent studies have shown that as income increases the greater is the consumption of milk, eggs, fruit, vegetables, meat and fish. This finding is not altogether new. It has long been established from the innumerable records of family expenditures published by the well-known economists of the nineteenth century that additional increases in income are associated with an increasing amount spent on food, and further, that the struggle to consume better kinds of nourishment is greater than the striving to increase total amounts of consumption. Le Play and Engel, who were the first to generalize these laws, maintained that the upper classes were to be differentiated from the lower by the amounts of animal food they consumed.

What is entirely new, however, is the realization that rising income, associated with increased consumption of milk, eggs, fruit and the rest, goes hand in hand with decreased death-rate, better growth of children, greater adult stature and much improved general health. The explanation of this lies in the fact that the foods mentioned are just those found to be richest in vitamins, mineral matter and first-class protein, constituents proved by laboratory experiments to be essential for the preservation of health. This is the crux of what has been called 'the newer knowledge of nutrition'. It calls for a change in point of view rather than any fundamental or revolutionary alteration in dietary habits.

Undoubtedly, disquieting features in the state of national fitness have been revealed as a result of these recent dietary and family budget investigations in Great Britain, and very naturally a lively public interest in the whole nutrition question has been aroused. Social conscience is especially sensitive because, not only in Great Britain but also in many other countries, it has been estimated that a very large proportion of the population falls into groups in which the income per head is less than that considered sufficient for the purchase of foods necessary for the maintenance of optimum health. The unfulfilled needs of the people of Great Britain for essential foodstuffs have been assessed at £200,000,000 a year.

Inevitably, controversy has arisen. On the question of needs, typical examples of disagreement are those which surround the standards advocated by expert medical opinion and those adopted by Government departments responsible for unemployment assistance and other forms of public relief. In official circles the inclination has been to think in terms of minimum needs; that is to say, the level fulfilling conditions which would keep the population at the present average standard of health and physique. The scientific investigator, on the other hand, cannot conscientiously study anything less than an optimum, which has been defined as a level of requirement above which no subsequent addition would add to the individual's share of good health and of full physical development. Again, the absence of precise objective standards by which to measure the state of nutrition of a given individual offers another serious difficulty. The adoption of differing standards and the varying mental conceptions and impressions of individual observers have led to confusion in the assessment of malnutrition and the subsequent comparison of data from different sources. As a result, allegations that substantial and progressive declines in the health of communities have followed the years of economic depression are often difficult either to refute or to substantiate. Further fuel has been added to the fire of controversy by the expressed opinion of statisticians that some of the most recent contributors to the discussion on the relation between poverty and nutrition have based their findings on faulty methods and meagre and uncertain data.

The task of those who would distinguish what is true from what is false is not made any easier by the number of different bodies, official and non-official, which have contributed to the discussion. Data from all sorts of different sources—medical, chemical, physiological, social—have been accumulated piecemeal.

Questions of nutrition now regularly form an outstanding feature of the official reports, issued from

the Ministry of Health and the Board of Education, dealing with the state of national health and the welfare of infants and school children; and, year by year the number of local authorities which have instituted inquiry into nutritional conditions in their own areas becomes greater and greater. Further, in Great Britain at any rate, there have arisen within the last few years numerous semi-private organizations the self-imposed task of which is partly to educate the 'man in the street' upon what is properly considered to be a matter of immediate public concern, and partly to stimulate official circles into making authoritative pronouncements regarding what constitutes an adequate diet and how the Government proposes to bring such a diet within the economic compass of every section of the community. Chief among these are: the Committee Against Malnutrition, the Children's Minimum Council, the People's League of Health, and PEP (Political and Economic Planning), all of which have, by well-directed propaganda and other means, done much to focus public attention on the urgent need for the formulation of a sound national nutrition policy.

Whatever may be one's opinion on the validity of individual statistics purporting to show the extent of malnutrition and its precise relationship to family habits and circumstances, there is no doubt that, viewed in the widest perspective, a serious amount of malnutrition prevails in almost every country in the world, especially among children. Furthermore, it seems that where the dietary standards fail, the major cause is not ignorance but poverty.

It is not surprising, therefore, that following the presentation of facts there should have been a cry for official action. Before action can be taken, however, the public health administrator must satisfy himself that the principles suggested to him by the scientific investigator do really concern him. Broad generalizations must be accepted with caution. Alarmist statements on the prevalence of under-nutrition must be considered judiciously. Facts must be verified and must be interpreted with greater precision in order to determine whether action is justified and what form it should take. The tendency in Government circles, therefore, has been towards further inquiry rather than to the hasty acceptance of the new ideas.

In the United Kingdom, the Minister of Health and the Secretary of State for Scotland appointed, in May 1935, an Advisory Committee to examine the quantitative and qualitative facts of nutrition and to report as to any changes in the diet of the people which might appear desirable in the light of modern advances in our knowledge. This Committee has recently issued its first report, the out-

standing features of which are the Committee's adoption of the standards of dietary requirements drawn up by the League of Nations Committee to which reference is made below, its recognition of the importance of milk and its recommendation that in impending legislation dealing with the national milk supply the primary objective of the Government should be to ensure that specified amounts (two pints per day for every pregnant and nursing mother, and a pint and a half for every child) are brought within the purchasing power of the poorest. It has also accepted as reasonable and likely to be in accordance with the facts, the broad picture on food consumption at different income levels prepared by the Market Supply Committee and used by Orr as the basis of his estimates in "Food, Health and Income"; but recommends that it should be regarded not as final but rather as a framework to be filled in when an adequate number of budgets have been obtained and individually analysed. These are conclusions of far-reaching importance.

Of much wider interest, however, is the attention which has been paid to the nutrition question by the League of Nations. The Health Organisation has been engaged in the study of nutrition in its relation to public health since 1925. On the proposal of the Australian delegate, who, incidentally, was one of the first to appreciate the close nexus of interest between problems of health and agriculture, the League, at its sixteenth Assembly in 1935, recommended that the Health Organisation should continue and develop its work on nutrition in collaboration with the International Labour Office and the International Institute of Agriculture. At the same time, the Assembly decided upon the creation of a Mixed Committee of experts on agriculture, economics and public health, charged with the duty of presenting a general report to the Assembly on the problem of nutrition in its public health and economic aspects. The nineteenth International Labour Conference adopted a similar recommendation. In October 1935, the Health Committee decided to set up a Technical Commission on Nutrition composed of three experts each from the United Kingdom, the United States and France, and one from each of six other European countries. This Commission, at its first session in London in November 1935, laid down the physiological bases of nutrition and established the food requirements of human beings during their growth from conception until adult age. With a view to the application of these recommendations in different countries and their adaptation to varying geographic, economic and social conditions, the report was circulated for the observations of academies of medicine, research councils and other authorities in various countries.

the competence of which covers nutritional problems. At its second session, held in Geneva in June 1936, the Technical Commission examined the observations communicated by these bodies, revised and amplified its London report, and presented it to the Mixed Committee in conformity with the Assembly's resolution of 1935.

This revised report, embodying considered international opinion on human dietary standards, represents the first and most outstanding contribution towards evolving order out of the chaos of specialized data on requirements which has confronted nutritional workers in recent years. A yardstick has at last been provided by which to measure diets and determine how far they are deficient for health. As already mentioned, the report has been adopted by the Advisory Committee on Nutrition responsible to the British Ministry of Health, and, in common with all the other work of the League's Technical Commission on Nutrition, has created a considerable impression not only in Europe but also over-seas. Thus, items included on the agenda of the Inter-Governmental Conference of Far-Eastern Countries on Rural Hygiene have been inspired by the Commission's work, as also has the recent formation of numerous national councils, such as those in Australia and in the British Colonies, specially set up to study local nutritional problems along the lines of the League's recommendations.

Perhaps nowhere have the suggestions of the League been acted upon with greater promptitude than within the British Colonial Empire. In April 1936, the Secretary of State for the Colonies addressed a dispatch calling for a comprehensive survey of the nutrition position in each Dependency. One of the main purposes of the dispatch was to direct attention to the important bearing which nutrition should have upon agricultural, veterinary, educational and general policy in the Colonial Empire. In planning the production of any territory the aim should be twofold; on one hand, the provision to the entire population of a

locally grown food supply considered adequate by medical science and, on the other, the growth of remunerative export crops. Already many replies have been received, some of which have been made available as public documents. "Food in Relation to Health" has been issued by the recently established Nutrition Committee in Trinidad; a similar report, based on the well-known work of Nicholls, describes conditions as they apply in Ceylon; the report of a specially formed nutrition committee has been presented to the Legislative Council of British Guiana; and a "Nutritional Review of the Natives of Zanzibar" has also been submitted.

To consider these reports and to advise generally on nutritional matters relating to the British Colonial Empire, the Prime Minister, in November 1936, appointed a Committee of the Economic Advisory Council consisting of medical, agricultural and economic specialists. This Committee is expressly commissioned to keep in touch with the work of the League of Nations and enable His Majesty's Government to assist and support it more effectually.

No attempt has been made here to deal exhaustively with the subject under review. Rather the aim has been to present a brief general outline touching the reasons for, and the nature of, Government intervention and official international co-operation on a subject of intense universal interest. Unavoidably, the writer's approach has been from the British point of view. One must remember, however, that in the United States of America, in the U.S.S.R., in Italy and in many other countries, evidence that Governments have accepted their obligations to give authoritative public guidance on questions of nutrition is equally conspicuous.

By far the most important thing is that the League of Nations has been accepted as the common platform on which national aspects of the problem can be debated in their world setting and in an atmosphere of reason and mutual comprehension.

Obituary Notices

Prof. J. W. Michaelsen

PROF. J. WILHELM MICHAELSEN, *Hauptbustos* in the Hamburg Zoological Museum, died on February 18 in his seventy-seventh year. Born in Hamburg, he joined the Hamburg Museum in 1887 and worked there until the time of his death. As a young man he became interested in the Oligochaeta, and from 1886 until his death he wrote many papers on their anatomy, classification and geographical distribution. He also wrote on the Tunicates and the Polychaeta,

but his main interest was the Oligochaeta, and it would be difficult to over-estimate the extent of his contribution to our knowledge of this group. Vastly learned, disinterested and careful of minutiae he belonged to the great tradition of German scholarship, and the sheer quantity of his work—his papers on the Oligochaeta alone bind up into eight very bulky volumes—testifies to an extraordinary industry and persistence of motive. In addition to this, he found time to make journeys to the southernmost corners

of America, Africa and Australia in pursuit of evidence to throw light on the palaeogeographical problems arising out of his study of Oligochoeta distribution.

There has never been any question as to the consistently high quality of Michaelsen's work, and his co-specialist and in his own line his only peer, the late J. Stephenson, has for a heading to his monumental monograph on the Oligochoeta (Oxford Univ. Press, 1930) the words, "To my Friend and Master W. Michaelsen of Hamburg".

Those of a younger generation who had the good fortune to correspond with Michaelsen will testify to his great kindness and patience. Even when he was a man in the seventies he would go to extraordinary lengths to assist a beginner who applied to him for help or information. On one occasion, he copied out a whole paper himself by hand and traced the drawings to send to a young student who wrote to say that the particular work was not available. He had the rare characteristic of cheerfully acknowledging his own mistakes, and was entirely free from that failing which overtakes so many men who have devoted their lives to the mastery of a specialism, the failing which consists in treating a difference of opinion, especially one coming from a younger man, as a personal affront. His letters reveal a simple, unexpectedly humorous and kindly man.

Prof. A. Erman

THE death of Prof. Adolf Erman on June 26 inflicts an incalculable bereavement upon both the Egyptological world and a large circle outside it. In the realms of his own subject he was without doubt regarded as the foremost scholar, since it was he who first placed the study of the ancient Egyptian language upon a scientific basis. His "Ägyptische Grammatik", which first appeared in 1894 and which was destined to pass through four editions, revolutionized the method of approach to the classical language, while the later phase of Egyptian, known as "New Egyptian", was fully dealt with in his "Neuägyptische Grammatik" of 1890 and 1933. Yet he was far from belonging to that class, all too large even at the present day, of specialists who never trouble to interpret their discoveries for the benefit of the general reader. He could write excellent descriptive prose, informed by a considerable sense of humour, which presented a living picture to his readers, as in his "Ägypten", translated into English by Lady Tirard under the title of "Life in Ancient Egypt", his "Religion der Ägypter", translated by the same author and called "Handbook of the Egyptian Religion", and his "Literatur der Ägypter" of which the English edition has been prepared by Prof. A. M. Blackman. The last-named book is perhaps his greatest contribution of this kind, enabling the student of the past for the first time to become acquainted with specimens of ancient Egyptian literature of all periods, beautifully translated and explained.

The greatest of Erman's undertakings, however, was the enterprise of the Berlin hieroglyphic diction-

ary, which he edited jointly with other colleagues. This vast work, intended to cover the whole history of ancient Egyptian, is still in process of publication, the first five volumes having appeared between the years 1926 and 1931. It has been justly said that the wide range of Erman's abilities made him an interpreter of Egyptian civilisation unrivalled by any other except the Frenchman Gaston Maspero. He has left to his successors a standard of scholarship which can only be maintained if the scientific principles which he so assiduously taught during his long life are faithfully obeyed. A. W. SHORTER.

WE regret to announce the death on August 3 of Prof. Josef Woldfich, director of the State Geological Institute at Prague, at the age of fifty-seven years. Born in Vienna, Prof. Woldfich became well known in Central Europe for his geological investigations, which began with a re-examination of certain Bohemian rocks, notably those studied by the Frenchman Barrande and more recently by the late Prof. J. E. Marr of Cambridge. After the Great War, he was appointed to the chair of geology at the new University of Brno in Moravia. Here he commenced a series of geological studies of the lesser-known districts of Slovakia, a work of extreme importance for the compilation of the modern geological maps of Czechoslovakia. He had been director of the State Geological Institute for the past three years.

We regret to announce the following deaths:

M. André Beaumont (M. Jean-Louis Conneau), one of the pioneers of aviation, aged fifty-seven years.

Dr. W. M. Cumming, lecturer in bacteriology in University College, Dundee, an authority on tuberculosis, aged thirty-nine years.

Mr. C. E. L. Gilbert, C.I.E., formerly chief conservator of forests, Bombay Presidency, on August 8.

Prof. Vernon L. Kellogg, professor of entomology in Stanford University in 1896-1920, permanent secretary of the U.S. National Research Council in 1920-32, aged sixty-nine years.

Prof. Hans Reek, the distinguished German volcanologist, who was associated with the discovery of human remains at Oldoway, Tanganyika, in 1914, on August 4, aged fifty-one years.

Prof. A. E. Seaman, emeritus professor of geology and mineralogy in the Michigan College of Mining and Technology, on July 9, aged seventy-nine years.

Mr. A. Sharples, formerly Government mycologist, Federated Malay States, and head of the Division of Plant Pathology, Rubber Research Institute of Malaya, on August 6.

Mr. J. W. N. Sullivan, author of "Three Men Discuss Relativity" and other books of a popular character on aspects of modern science, on August 12, aged fifty-one years.

Prof. J. G. Thomson, professor of medical protozoology in the London School of Hygiene and Tropical Medicine, on August 13.

News and Views

The Sun's Outer Envelope

ACCORDING to a cabled statement from the New York correspondent of *The Times* published on August 14, Major Stevens of the United States Army, flying over Peru at a height of 30,000 ft. on June 8, during the total solar eclipse, obtained some very surprising photographs of the eclipsed sun. Surrounding the corona with its irregular streamers, there was found a bright envelope one million miles high in which the details of the corona became insignificant. The first natural reaction is to ascribe this result to photographic effects of over-exposure, especially as no details of the size of the image secured or other optical details of the apparatus used are given. But the name of Harvard University behind the announcement renders one unwilling to look to any simple instrumental explanation of this unexpected phenomenon. A link between the corona and the zodiacal light seems suggested, but no indication is given in the report of any extension in the zodiacal plane, such as would be expected. Again, since the zodiacal light and the corona both have the same distribution of radiation as ordinary sunlight, one would expect any connecting matter to be similarly conditioned. Only over-exposure, which blots out all coronal details, would account for the even globular envelope unless this outer envelope is relatively much stronger in light of short wavelength. It would be interesting to know what visual observations were made from the aeroplane. If these agreed in general outline with the photographs secured from the ground, then the photographs from the stratosphere suggest an extensive outer atmosphere giving bright line or bright band radiation which must be examined spectroscopically at the next suitable total eclipse. Further and fuller details of the photographs will be impatiently awaited.

Anglo-Egyptian Treaty Honours List

THE additional Egyptian Honours List issued in connexion with the signing of the Anglo-Egyptian Treaty in London, and published in the *Egyptian Mail* of July 28, contains the names of the following men of science: *Third Class of the Order of Ismail* (Commander), Dr. E. Hurst, director-general of the Physical Department of the Ministry of Works, and Mr. F. Newhouse, inspector-general of irrigation in the Sudan; *Second Class of the Order of the Nile* (Grand Officer), Dr. Roy S. Dobbin, professor of obstetrics in the Egyptian University, Cairo; *Third Class of the Order of the Nile* (Commander), Dr. J. Templeton, chief botanist, Botanical and Plant Breeding Section, and Dr. W. T. H. Williamson, chief chemist, Chemical Section, of the Ministry of Agriculture, Dr. J. H. Grindley, expert for technical education, Major W. L. Forsyth, professor of bacteriology, and Prof. D. H. Bangham, dean of the faculty of science in the Egyptian University, Cairo; *Fourth Class of*

the Order of the Nile (Officer), Mr. G. H. Jones, director of the Mycological Section, Prof. H. Priesner, director of entomological research, and Mr. C. H. Broun, senior botanist of the Ministry of Agriculture, Prof. T. L. R. Ayres, professor of physics, Dr. O. Zdanaki, professor of geology, and Prof. A. Naef, professor of zoology in the Egyptian University, Cairo.

Centenary of Dr. Edmund Weiss (1837-1917)

ON August 26, 1837, Dr. Edmund Weiss, the distinguished Austrian astronomer, was born at Freiwaldau, in Austrian Silesia. A part of his boyhood was spent in England, where his father was physician to a health institution, but he received his education at Troppau and at the University of Vienna, and at nineteen years of age became assistant to Karl von Littrow (1811-77) in the old Vienna Observatory which had been erected in 1826 by Joseph von Littrow (1781-1840) on the site of the observatory established by Father Maximilian Hell, S.J., in 1758. At first Weiss was employed on geodetic work, but it being proposed to remove the old observatory, which was situated among the narrow streets of the Austrian capital, to a more favourable situation, Weiss, in 1872, was sent on a tour of European and American observatories to study their methods, and optical works, and to him fell the task of planning the equipment of the new observatory at Währing, the foundation stone of which was laid in June 1874. On von Littrow's death in 1877 Weiss was appointed to the directorship. This post he held for thirty-two years, retiring in 1910. He died on June 21, 1917, at the age of seventy-nine years. During his career Weiss took part in several eclipse expeditions, was one of the observers of the transit of Venus in 1874, wrote on comets, meteors and orbits, and prepared a revised edition of Oeltzen's catalogue of Argelander's zones from 15° to 31° S. declination. He was a member of the Vienna Academy, a *correspondant* of the Paris Academy of Sciences, and for thirty-four years an associate of the Royal Astronomical Society.

Reginald Harrison (1837-1908)

MR. REGINALD HARRISON, who was equally eminent as a Liverpool and as a London surgeon, was born at Stafford on August 24, 1837. He was educated at Rossall School and St. Bartholomew's Hospital, and qualified in 1859. In 1866 he became fellow of the Royal College of Surgeons, and the following year was appointed assistant physician to the Royal Infirmary, Liverpool, becoming full surgeon in 1874. He was at first a general surgeon, but before long he specialized in diseases of the male genito-urinary system, and in 1889 he left Liverpool for London on his appointment as surgeon to St. Peter's Hospital for Stone and Other Urinary

Diseases. Harrison was the author of "Surgical Disorders of the Urinary Organs" which became a standard text-book, and went through four editions, as well as of "Selected Papers on Stone, Prostate and Other Urinary Diseases" and "The Use of the Ambulance in Civil Practice". During his residence in Liverpool he re-organized medical education at the Royal Infirmary, and took an active part in the introduction of the ambulance system, in which he continued to take an interest after his removal to London, being president of the Street Ambulance Association at the time of his death. He was the recipient of many distinctions, including those of Knight of Grace of the Order of St. John of Jerusalem, president of the Medical Society of London, and Hunterian professor of surgery and pathology of the Royal College of Surgeons. In 1903 he inspected the School of Medicine at Cairo for that College and received the Imperial Ottoman Order of the Medjidie.

Roman Dorchester

THE Dorset Natural History and Archaeological Society, concurrently with its share in the excavation of Maiden Castle, is investigating a site at Colliton Park, Dorchester, on which a county hall is to be erected. The site is within the walls of the Roman city and has not been built on since Roman times. In view of its situation, it was thought probable that Roman buildings would be found there, and the last opportunity upon which the site would be available for examination could not be allowed to pass by. Already, it is reported (*The Times*, Aug. 14), a large part of a house has been disclosed, of which one range of five rooms contains three for bathing, a central dressing-room, with a hot bath on one side with its hypocaust, still largely intact, and on the other side the cold bath-room. North of this range of rooms is a corridor looking out on the courtyard, in which is the well, now cleared to a depth of thirty feet. The filling of the well was found to be entirely composed of wreckage from the building, and included broken parts of at least nine stone columns, four of which are complete though fractured. They probably formed the colonnade of the corridor. At right-angles to the first range of rooms is a second, consisting of seven rooms. All these have mosaic floors, of which one is in perfect condition, while another, though badly damaged, still shows traces of considerable beauty. This latter has panels containing a head of Flora and another head which has not yet been identified. One of these rooms has a hypocaust beneath. An unusual feature in a Roman house in Britain is the lower part of two windows with internal splays. As this house is clear of the building line of the new hall it is hoped to preserve it intact. Trial trenches are being dug to find the other buildings which are thought to lie beneath the surface. As the whole area is to be explored, further financial assistance towards the considerable cost is required.

The Gyro Compass on the Hudson Bay Route

IN a summary of the eighth report of the Imperial Shipping Committee on Hudson Bay Marine In-

surance Rates, published by H.M. Stationery Office, 3d. net, which appears in *The Times* of August 13, it is mentioned without comment that the Committee quotes tributes by captains of ships to the value of a gyro compass in contributing to the confidence with which the Strait and Bay were navigated. It is stated that other masters have expressed the view that a gyro compass is essential for navigating the Hudson Bay with safety. The Committee submitted to the underwriters that a further reduction of premiums should be made in respect of vessels equipped with gyro. An illustration is given of the saving of premium which could be effected by installing a gyro compass for one voyage, two voyages, and three voyages in the same season; against this is set the cost of hiring a gyro compass for, say, three months, which including fitting would, it is stated, be approximately £200, plus a very small charge for inspection. The Committee concludes that there is now a considerable inducement to the owner of a vessel to instal a gyro compass for voyages to the Hudson Bay. A gyro compass is specially desirable in the Hudson Bay area on account of the proximity of the north magnetic pole, off the Prince of Wales Land; a ship entering Hudson Bay must approach this pole within at least 14° , and owing to the low value of the horizontal magnetic force (which becomes zero at the magnetic pole), the directive force on the compass is low, and disturbances have a proportionately large effect. On the other hand, the distance from the geographical pole, which is one of the factors in determining the directive efficiency of the gyro compass, is more than 25° .

Electricity and Marketing

AN account is given of the Farmer's Conference at the Royal Agricultural Show held at Wolverhampton on July 8, in the *Electrician* of July 16. Mr. F. H. Slade read a useful practical paper on "Electricity and Marketing". He said that now the rural distribution of electricity is extending so rapidly, the British farmer will be able to compete on better terms with the foreigner. He described machines for the electro-mechanical grading and packing of fruits. Such machines will grade in one hour 700 lb. of gooseberries or 1,400 lb. of plums or 180 boxes of tomatoes, without bruising them and with less loss of bloom than by hand methods. A $1\frac{1}{2}$ h.p. electric motor can divide hard fruit into fine sizes and two qualities at the rate of 1,000 bushels per day, ready for cold storage. It pays a grower having 20 acres or more to instal grading and refrigerating plant. The care of apples in a refrigerator is a matter of 'atmospheric control'. In a suitable atmosphere the fruit can have its life-cycle speeded up fifty per cent or the ripening of the fruit can be slowed down by fifty per cent. The average cost of cooling milk in a refrigerator for dairy purposes costs on an average about a penny for thirty gallons. Refrigerated stores for eggs are replacing water-glass immersion. Thanks to electricity, the British farmer, instead of merely getting low prices in season and losing markets out of season to foreign competitors, is now in a much

better position to get profitable returns. Mr. Borlase Matthews mentioned that eight years ago there were 600 British farmers using electricity; the number now is more than 30,000. He mentioned that electricity was available to every exhibitor in the Show and for the first time they had a telephone exchange in the Show yard.

Practical Difficulties in International Telephony

In Europe, telephone operation is mostly in the hands of State administrations, although there are some large private telephone undertakings. To ensure satisfactory international joint working, uniform provisions for the calls are an indispensable necessity. With this end in view, the International Consultative Committee for Telephony, known as the C.C.I.F., has drafted recommendations and working instructions intended for application to international telephone traffic. In the *Brisson Review*, No. 1, 1937, Mr. A. Lignell, director of telephones at Stockholm, discusses these recommendations from the point of view of practical operation. He points out that an international call makes use of the subscriber's line, the exchange equipment at both ends and one or more international lines, as well as two or more operators for making the connexions. This type of call is much more difficult to deal with both in respect of time occupied and handling than a local call, and as a rule is of greater importance than a purely local connexion. The C.C.I.F. has therefore recommended that a local call ought to be cut off to allow of an international call, and this is prescribed in its "instructions to operators". At the plenary meeting of the C.C.I.F. in Copenhagen in 1936, there was formulated a question to the following effect, namely, whether international calls should be established with the "least possible delay", instead of connecting them immediately, and so simplifying and cheapening the equipment of local and trunk exchanges. Mr. Lignell is afraid that such simplification would lead to appreciable economic and other disadvantages in international traffic. At the present costs of trunk lines, this seems inevitable. It is to be hoped that the priority over internal traffic which international regulations accord to international traffic may be maintained.

Illuminated Show Cases

When lamp fittings are used in the normal way, electricians usually assume that the ambient temperature is about 27° C. and this gives a rise of 23° C. in the connecting leads before the maximum permissible operating temperature (50° C.) of the rubber insulation is attained. If the lamp fittings are used in enclosed shop windows or show cases, the assumption about the ambient temperature is no longer valid, as it depends on the aggregate wattage of the lamps in the enclosure. In a technical report of the Electrical Research Association (E.R.A.) published in *World Power* of April, a very thorough research by H. G. Taylor, W. J. Fehrsich and the late P. D. Morgan has been made to find out the actual heating

and to suggest methods of reducing the ambient temperature when excessive. Four methods are considered. A fan can be used to disturb the air, and so provide a uniform temperature throughout the enclosure. Another method is to provide natural ventilation by holes at the top of the case for egress of the hot air and others at the bottom for ingress of the cold air. Forced ventilation may also be used. The last method considered is to use special glass which either transmits the infra-red rays emitted by the lamps, etc., or has a high thermal conductivity and so facilitates the transfer of heat from the inside to the outside of the show case. The first two methods were found to be of considerable value. It was found that if the area of the holes bored in the top and bottom of the show case was about 4 per cent of the area of the top and bottom, the maximum temperature rise was reduced by fifty per cent.

Oil Transport in the Middle East

So far as is known, the large oil-fields of the Middle East are situated in Iran and Iraq. In Iraq the principal producing field is in the neighbourhood of Kirkup to the east of the Tigris and 145 miles north of Bagdad. In Iran, oil is derived mainly from two large oil-fields. The exploitation of petroleum on a modern commercial scale in these countries is a very recent development which is producing social changes in the ways of the inhabitants, and in the economic sphere it is widening the basis of trade, increasing the revenue and bringing money into the country. In the Year Book of the Cambridge University Engineers' Association for 1936, Colonel H. E. Medlicott describes the engineering difficulties of constructing 1,600 miles of roadway in Iran, sometimes skirting precipitous hillsides. The Anglo-Iranian Oil Company has already raised more than seventy million tons of oil from the two main oil-fields. In Iraq, the Iraq Petroleum Company had under its concession to construct a pipe-line system from Kirkup to the Mediterranean. It was decided that the line should debouch at two points on the Mediterranean, Haifa to the south and Tripoli to the north. The distance along the pipe-line route from Kirkup to the Euphrates is 156 miles, and from there two sections bifurcate, the southern section going to Haifa and the northern section traversing Syria to Tripoli. The crossings of the Tigris and the Euphrates had to be made by 'Blondins' (overhead cable ways) and steel towers about 140 feet in height had to be erected in concrete to support the massive steel ropeways over the rivers which carried loads of ten tons from one bank and deposited them on the other. The author is strongly of the opinion that the Middle Eastern history of the near future will be a record of steady progress, sociologically, economically and politically.

Mining and Geology in South Australia

We have received the annual report of the Director of Mines and Government Geologist of South Australia for 1935 (Adelaide: Government Printer, 1936). After a lengthy list showing that more than a hundred

plaints were investigated by the wardens, there is a series of short reports concerning mineral deposits, of which the most interesting is probably that "the Government Geologist was appointed to the Geological Advisory Committee assisting the operations of the Anglo-Persian Company's geologists who are making an examination of Australian territory for The Commonwealth Oil Refineries Ltd." This is followed by a report of the chief inspector of mines on the inspection work, whilst the general manager gives a report of the operations of State batteries and cyanide works. The mineral production of 1841-1935 closes the report, and shows a value of only a little more than 55 million pounds, of which three fifths is derived from copper ore and a quarter derived from iron ore. We have also received the Mining Review (No. 64) for the half-year ending June 30, 1936, of the South Australian Department of Mines. The review records the progress of mining operations in the first half of last year. The large-scale operations at Iron Knob and the many small gold mines scattered throughout South Australia are particularly noted.

The Problem of Reality in Physics

THE April number of *Current Science* contains a report of a lecture delivered at the Indian Institute of Science, Bangalore, by Prof. R. Ortvy, of Budapest, on "The Problem of Reality in Physics". Prof. Ortvy outlined the positivistic and realistic attitudes in physical science, the contrast between which he described as analogous to the relation between nominalism and realism in philosophy. To the positivist our only direct data are sensations, which alone constitute physical reality. All other 'existence' is constructed mentally out of sensations, and possesses a lower degree of importance. It follows that it is a senseless question whether anything exists that cannot be observed. This doctrine originated with Mach, and is shared by Bohr, Heisenberg, Dirac, Schrödinger and Philipp Franck. On the other hand, physical realism, the chief representatives of which in physics are Planck, Laue and Sommerfeld, chooses as its fundamental task the construction of a description of the world which is independent of our individuality. In Prof. Ortvy's opinion, positivism and realism are ultimately equally legitimate, just as in a logical system it is to a certain degree arbitrary what is to be considered as belonging to the basis of the system and what as a deduction. Positivism, in the form which was developed under the influence of quantum mechanics, leads to a profound change of our idea of the physical state of a system, but does not destroy the notion of the objectivity of a state, and so is not beyond realistic expression. On the other hand, Prof. Ortvy does not agree with the identification of observability and existence. He believes that we must maintain that certain things exist which can never be observed.

Research on Radium Therapy

RADIUM therapy in Great Britain was given a great stimulus with the formation of the Radium Beam

Therapy Research unit towards the end of 1933. A series of papers during the last two years shows valuable contributions on many sides of the subject. Two of these papers have appeared in *NATURE*, one in the *Journal of Scientific Instruments* upon the properties of a new tungsten-nickel-copper alloy, the remaining seven in the *British Journal of Radiology*. Most of these papers are contributed by physicists, and deal in an exhaustive way with the physical properties of the radiation used and its intensity variations among the tissues that it penetrates. One paper, entitled "Delivery, Estimation and Control of Tissue Dosage in Radiation Therapy", by C. A. P. Wood and T. A. Green, exhibits in the most happy way how the carefully acquired physical data are being put to the direct service of the clinic. This paper may be said to mark an advance in the development of the use of big radium units in the treatment of cancer. The paper shows the importance of a knowledge of the state of radio-sensitiveness of the tumours being treated and how a best selection of the ports of entry of the radiation can only be made by those having the necessary anatomical knowledge combined with experience of the various modes of spread of cancer.

Indian Science Congress Association: Silver Jubilee

THE twenty-fifth annual session of the Indian Science Congress Association will be held in Calcutta on January 3-9 under the presidency of the Right Hon. Lord Rutherford. To mark the silver jubilee of the Association, the meeting is to be a joint session with the British Association. About a hundred men of science have been invited from Great Britain, while invitations have also been extended to a number of scientific workers in other countries. The Congress will be divided into the following sections under the presidents named: (1) Mathematics and Physics, Dr. C. W. B. Normand, director-general of observatories, Meteorological Office, Poona 5; (2) Chemistry, Prof. S. S. Bhatnagar, director, University Chemical Laboratories, Lahore; (3) Geology, Mr. D. N. Wadia, officiating superintending geologist, Geological Survey of India, 27 Chowringhee, Calcutta; (4) Geography and Geodesy, Dr. A. M. Heron, director, Geological Survey of India, 27 Chowringhee, Calcutta; (5) Botany, Prof. B. Sahni, professor of botany, University of Lucknow; (6) Zoology, Prof. G. Matthai, professor of zoology, Government College, Lahore; (7) Entomology, Mr. M. Afzal Husain, principal, Punjab Agricultural College, Lyallpur, Punjab; (8) Anthropology, Dr. B. S. Guha, Zoological Survey of India, Indian Museum, Calcutta; (9) Agriculture, Rao Bahadur T. S. Venkatraman, Imperial sugar-cane expert, Lawley Road, Coimbatore; (10) Medical Research, Sir Upendranath Brahmachari, professor of tropical medicine, Carmichael Medical College, Calcutta, and honorary professor of bio-chemistry, University of Calcutta; (11) Veterinary Research, Sir Arthur Oliver, animal husbandry expert, Imperial Council of Agricultural Research, New Delhi; (12) Physiology, Col. R. N. Chopra, officiating director and

professor of pharmacology, School of Tropical Medicine, Calcutta; (13) Psychology, Dr. G. Bose, University College of Science, 92 Upper Circular Road, Calcutta. The main part of the British Association delegation will arrive at Bombay on December 16, and will tour Northern India before attending the Congress. The address of the General Secretary of the Indian Science Congress Association is c/o The Geological Survey of India, 27 Chowringhee, Calcutta.

Lubrication and Lubricants

THE *Journal of the Institution of Mechanical Engineers* of May describes the arrangements which have been made for a general discussion on lubrication and lubricants which is to take place at the Institution on October 13-15. The executive committee, with Dr. H. J. Gough as chairman, desires to make this an opportunity to review the present state of knowledge on the subject by means of contributions from those who are especially qualified to discuss the major problems, the immediate objects being to establish a correlation between theory, academic research and trade practice, to elucidate the methods of design of bearings, to obtain current views upon bearing metals and to explore the significance of laboratory tests. In connexion with the meetings, it is proposed to organize an exhibition. In view of the importance of the subject, the active co-operation of other societies has been invited and already more than forty British and foreign institutions have accepted. The programme, in its present state, contains about a hundred papers divided into four distinct groups dealing respectively with journal and thrust bearings, engine lubrication, industrial applications, and properties and testing, each of which has been split up into appropriate sections and subsections. From these it would appear that no aspect of the widespread applications of lubrication has been lost sight of, and besides those problems and considerations associated with all classes of machinery, such cases as those arising in connexion with wire-drawing, wire rope transmission, chains, metal pressings, cutting fluids and the like are to be subjects of discussion. In the group comprising properties and testing, the papers will deal with three main sections under the headings friction and wear, physical properties, and chemical properties. The papers already promised are being prepared by leading authorities on their subjects, and it is desired that further offers to contribute to the discussion should be addressed to the secretary, The Institution of Mechanical Engineers, Storey's Gate, London, S.W.1.

Sphinx

THE problem of publishing results too specialized for such a journal as *NATURE* and not substantial enough for the proceedings of a learned society, which nevertheless have some permanent value and deserve to be recorded, is difficult. Many a pertinent observation must be buried in field-club notes in the files of local weeklies, and a glance at the pages of Dickson's "History of the Theory of Numbers" will

suggest the magnitude of the task of the conscientious historian in any subject in which isolated statements can be significant. These remarks are prompted by the appearance recently in *Sphinx*, a monthly devoted to mathematical recreations and published privately by M. Kraitshik, Institut des Hautes Etudes de Belgique, 65 rue de la Concorde, Bruxelles, of an article "On Hyper-Exponential Numbers", in which Mr. H. J. Woodall, formerly associated with Lieut.-Colonel Cunningham in a series of extensive computations, discusses some sequences which resemble the sequence of functions forming the exponential scale but replace the e of the analyst by an integer. Mr. Woodall gives specimens of classification, determines a few orders of magnitude, and finds a few inequalities. No better medium of publication exists for such work, but the fact remains that a future investigator is much more likely to repeat Mr. Woodall's calculations than to discover that the work has been done.

Bleaching of Wood-pulp

IN connexion with the article on "Wood Pulp and the Future" (see *NATURE*, 139, 867, May 22, 1937) we have received a letter from the Development and Research Department of the Pennsylvania Salt Manufacturing Co., 1000 Widener Building, Philadelphia, pointing out that the use of an emulsion of chlorine in water in multi-stage bleaching processes is the result of investigations made by this Company and is patented in twelve countries. It may be stated that the writer of the article was fully aware of the part played by the organization concerned in developing this particular method of bleaching. In a short survey covering such a wide field, however, it was not considered necessary to give references to the work of individual firms; in the case of bleaching processes in fact, this would indeed have been a particularly difficult matter, owing to the large number involved.

Genetical Society

THE summer meeting of the Genetical Society was held at the Courtauld Genetical Laboratory, Inner Circle, Regent's Park, on August 10. The demonstrations shown by Prof. R. Ruggles Gates and his staff included the following: many new species and varieties of *Abnothera*, in connexion with the genetic survey of the genus in eastern Canada; Indian and Japanese varieties of rice, with X-ray mutations, autotriploid and allotriploid progenies, showing an inverse relation between the number of extra chromosomes and the size of the plants; a cytological survey of various species of the Phalaridæ; cytogenetical studies of *Oicer aristinum*; experiments with the growth of pollen tubes in cotton plants, and a chromosome survey of various Malvaceæ.

Research on Mental Disease

THE annual report for 1936-37 of the Birmingham Joint Board of Research for Mental Disease consists entirely of pathological laboratory findings. Fifty-six named varieties of micro-organism are described as

occurring in the cavities or excretion of insane subjects and 769 tests were made of serological agglutination, though the absence of any record of control investigation among the sane population leaves the reader in difficulty as to the precise value of these results. The Board apparently does not concern itself with the psychological approach to the study of mental disease.

New Comet 1937 g (Hubble)

DR. E. P. HUBBLE, at Mount Wilson, discovered a new comet of magnitude 13 on August 4. Its position was R.A. $22^h 49.3^m$, S. Decl. 21° , and its daily motion $-30''$ in R.A. and $6'$ S. in Decl. Later observations have been made, but there is no mention of the positions, except one from Bergedorf. Cunningham and Shapley have computed the following orbit :

T	1937 Dec. 11.58	U.T.
ω	$54^\circ 54'$	} 1937.0
Ω	$11 \quad 12$	
i	$9 \quad 53$	
q	0.9010	

Its position in the constellation of Aquarius is not very favourable for observation in northern latitudes, and although it is approaching both the earth and the sun and will increase in brightness, it is not likely to become a conspicuous object. Its distances from the earth and sun at present are 1.1 and 2.1 units respectively, and on September 20 these will be 0.75 and 1.7 respectively.

Announcements

THE President of the French Republic has conferred the honour of La Croix de Chevalier de la Légion d'Honneur on Mr. Geo. E. Pearson, the governing director of the Wellcome Foundation, Ltd.

THE following appointments and promotions have recently been made in the Colonial Service: G. L. Carson, assistant conservator of forests, Malaya; W. P. Gaskell, inspector of mines, Nigeria; I. G. John, meteorological officer, Survey Department, Malaya; F. Birkinshaw (State agricultural officer, Perak), chief field officer, Agricultural Department, Malaya; W. G. Leckie (agricultural officer), senior agricultural officer, Kenya; J. N. Milsum (agriculturist), senior agricultural officer, Malaya; W. L. Watt (agricultural officer), senior agricultural officer, Kenya; M. E. Dommien (assistant conservator of forests, Cyprus), assistant conservator of forests, Nigeria; S. T. Phillips (inspector of plants and produce), senior inspector of plants and produce, Gold Coast; S. A. Roach (industrial instructor, Education Department, Tanganyika), livestock officer, Department of Agriculture, Sierra Leone; E. Wall (executive engineer, Public Works Department, Nyasaland), senior executive engineer, Public Works Department, Nigeria.

DR. THORVALD MADSEN, chief of the State Serum Institute of Copenhagen, has for the seventh time been elected president of the Health Committee of the League of Nations.

MR. FIORILLA H. LA GUARDIA, Mayor of New York City, recently laid the corner stone of a new health centre in New York, forming the ninth building which had been started under the plan of the New York City Department of Health to create full-time health districts.

AN international Congress of Tourism, Thermalism and Climatism will be held in Paris on October 14-17. Further information can be obtained from the Secrétariat Général de la Fédération thermique et climatique française, 127 Avenue des Champs Elysées, Paris VIIIe.

THE twenty-first International Congress against Alcoholism will be held in Warsaw on September 12-17 under the patronage of the President of the Polish Republic, with Dr. Chodsko, formerly Minister of Public Health, as president of the executive committee. The following papers, among others, will be read: "The Influence of Alcohol on the Brain", by Prof. Rose, of Wilno; "Wine as a Factor in Alcoholism", by Drs. Dauphin, Fillion-Roux and Faisant (France); and "Alcohol and Mental Disease with Special Reference to Beer as a Cause of Alcoholism", by Prof. Vermeulen of Brussels. Further information can be obtained from Dr. R. Hercood, La Glvoine, Epinettes, Lausanne.

MESSRS. BOOTS have issued a booklet dealing shortly with the use of protamine insulin (with zinc). It has a much more prolonged action than ordinary insulin, and is therefore more convenient to use. The booklet contains fourteen references to original papers, and may be obtained on application to the Wholesale and Export Department, Station Street, Nottingham.

"ZOOLOGIA SPECIALIS" is the title of a book catalogue (No. 711) issued by Gustav Fock (Leipzig), containing, amongst other items, books and papers from the libraries of the late Prof. G. Grimep of Leipzig and of Prof. L. Plate of Jena. The catalogue details 5,737 items, amongst which Vermes, Mollusca, Crustacea, Aves, Mammalia and scientific periodicals are especially well represented.

A SMALL book entitled "Clinical Colorimetry with the Pulfrich Photometer", compiled and published by Carl Zeiss, of Jena, in collaboration with Dr. W. Krebs (London: Carl Zeiss (London), Ltd.; W. and G. Foyle. 7s. 6d. net), gives details of a number of colorimetric tests applicable to clinical material. The technique of these tests is adapted for use with the Pulfrich stufenphotometer made by Messrs. Carl Zeiss. It will probably prove very useful to clinical pathologists.

ERRATUM.—In the fifth line from the bottom of the first column of p. 23 of NATURE of July 3, 1937, the names "Millikan and Cameron" should be replaced by "Bethe and Heitler". Millikan and Cameron have advanced no theory of showers.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 324.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

World-wide Effect in Cosmic Ray Intensity, as Observed during a Recent Magnetic Storm

MR. S. E. FORBUSH¹ noted a very striking similarity between the variation of the horizontal component of the earth's magnetic field intensity and of the intensity of the cosmic ray ionization (as registered by two Compton cosmic ray meters) at Cheltenham,

In Fig. 1 these values reduced to Greenwich Mean Time are plotted (thin curve) together with the bi-hourly means of the cosmic ray ionization on the Hafelekar, as registered with our Steinke standard apparatus shielded on all sides by lead (10 cm. thick) and in addition by iron plates (7 cm. thick). All values were reduced to standard pressure.

FIG. 1.
BI-HOURLY MEAN VALUES OF COSMIC RAY INTENSITY AND OF MAGNETIC HORIZONTAL INTENSITY,
APRIL 23 TO MAY 1, 1937.

•, Cosmic ray intensity, Huancayo. ○, Cosmic ray intensity, Cheltenham. —○—○—, Cosmic ray intensity, Hafelekar.

Maryland, U.S.A., and Huancayo, Peru, during the very severe magnetic disturbances between April 25 and April 30 of this year.

Our cosmic ray research station on the Hafelekar (2,300 metres above sea-level, near Innsbruck, Austria) gave results which corroborate Mr. Forbush's statements very strikingly. The magnetogram was taken from the registrations of the Vienna-Anhof Terrestrial Magnetic Station. We are obliged to Dr. M. Kofler, acting director of the Meteorologische Zentralanstalt, of Vienna, for placing the hourly values of the horizontal magnetic intensity at our disposal.

The variations of the ionization observed during the magnetically disturbed days (April 24–30, 1937) were uncommonly large: the maximum of the bi-hourly ionization means was 2,485 J. (April 24), the minimum 2,339 J., the deviations from the total average being +3.9 and –2.8 per cent respectively. Even the daily mean values varied by as much as +2.7 per cent (April 24) and –2.2 per cent (April 29).

In Fig. 1 the heavy-lined curve indicates our bi-hourly ionization values; the corresponding values of Cheltenham and Huancayo, indicated by small dots and circles in Fig. 1, were taken from Mr. Forbush's paper cited above.

In Fig. 1, Curves 1 and 2 represent the curves of the spectral sensitivity of plates sensitized with erythrocin and phloxine, reduced to the same number of incident quanta. Curves 3 and 4 represent the curves of absorption of these dyestuffs adsorbed on layers of silver bromide.

As it is to be seen from the figure, the wave-length of the maxima of sensitivity coincides exactly with the wave-length of the maxima of absorption of adsorbed dyestuffs (erythrocin, 558 m μ ; phloxine, 563 m μ) whereas the maxima of absorption of the dyestuffs in solution lie at 528 m μ for erythrocin and at 524 m μ for phloxine.

Glyceraldehyde and Embryonic Glucolysis

It has already been reported^{1,2} that anaerobic lactic acid production from glucose in the chick embryo is a true case of non-phosphorylating glucolysis, strongly inhibited by *D*-glyceraldehyde. As possible intermediates, glycerol, glyceric acid, dihydroxyacetone and methylglyoxal were excluded. We are now able to add to the list pyruvic acid and glyceraldehyde.* Of the two stereoisomers, *only* *L*-glyceraldehyde inhibits glucolysis; this corresponds in its configuration to *L*-lactic acid (sarcolactic acid) which derives from glucose in the body. The inhibitory effect is complete at a concentration of about 2.5×10^{-3} *M*. The fact that *D*-glyceraldehyde does not apparently inhibit glucolysis more than about 90 per cent is due to a slow enzymic lactic acid formation from glyceraldehyde itself. This process needs glutathione as co-enzyme and is not based upon a primary condensation of trioses to hexose, as it is not inhibited by amounts of fluoride or iodoacetate which would be enough to poison a secondary glucose breakdown. It is due rather to the non-enzymic formation of methylglyoxal under the experimental conditions, which is then converted to lactic acid by the glyoxalase present.

The exclusion of so many 3-carbon compounds as possible intermediates of glucolysis proper induces us to refer to the work of Nef³, who showed an *in vitro* intramolecular shifting of the enol linkage along the carbon chain in hexoses, and suggested a similar enzymic breakdown of glucose. Such shifting of enol-linkages would make it possible to understand how lactic acid can derive from *D*-glucose *in vivo*. The final step would be an intramolecular dismutation. The occurrence of enolization and dismutation would explain the inhibition of glucolysis proper by fluoride and iodoacetate, which also poison (though in different concentrations) the enolase and dismutase of hexosediphosphate breakdown.

Technique of the Painting Process

Vijayalaya Cholisvaram in Puducherry

THE ruined temple of Vijayalaya Cholisvaram is situated in the village of Narthamalai (10° 35' N. 78° 45' E.) in Pudukottah State in South India, being about five miles to the north-east of Sittar¹ and about 33 miles, as the crow flies, from Tanjore². The temple was probably built in the ninth century A.D. during the time of Vijayalaya, king of the Chola Dynasty of South India. Details of the paintings, however, have either faded or disappeared, due to the vicissitudes of time and environment, so that it is very difficult to judge of art as such. But circumstantial evidences go to show that the paintings were probably executed during the eleventh-twelfth centuries A.D., and at the same rate, their date cannot be later than the fourteenth century A.D. If they belong to the eleventh-twelfth centuries A.D., they should have been contemporaneous with the Chola paintings in the Brihadeswara temple³ at Tanjore.

The paintings are executed on the inner walls of the front hall of the temple, which are constructed of large blocks of hornblende-gneiss. The technique adopted is a combination of tempera with fresco. The painted stucco consists of the *Rinzaffo* or rough coat of lime plaster with a fine lime wash thereon, the latter having been applied while plaster was still wet. Over this is a layer of plaster of appreciable thickness. The thicknesses of different layers are: painted stucco, 3.3 mm.; rough plaster, 2.3 mm.; lime-wash, 0.4 mm.; plaster film, 0.6 mm.

The results of analysis of the rough plaster and paint film (red paint film being chosen for the purpose) are given in the accompanying table.

	Rough plaster (per cent)	Red paint film (per cent)
Moisture	1.30	1.71
Carbon dioxide	20.95	11.67
Loss on ignition	4.20	11.86
Silica (SiO ₂)	37.83	38.86
Iron and alumina (Fe ₂ O ₃ , Al ₂ O ₃)	1.79	7.63*
Lime (CaO)	31.73	25.09
Sulphuric anhydride (SO ₃)	0.03	0.17
Magnesia (MgO)	0.66	1.68
Undetermined (mostly alkalis)	1.33	1.24
	100.00	100.00

* Al₂O₃ being only 0.73 per cent.

The high value of the loss on ignition of the paint film, amounting to 11.86 per cent, is significant, goes to show the presence of organic matter in the paint film used as a binding medium.

The only inert material used with the lime is sand. So far as the pigments are concerned, lime has been used for the white, carbon for black, yellow ochres for yellow and red ochres for red and terre verte for green. There are traces of a light, bluish-grey colour, but sufficient quantity of it is not available for identifying the blue pigment.

Full details of the investigation will be published elsewhere.

of the Chicken Retina

Many bird and reptile retinas contain coloured oil globules. In the chicken they are red, golden and yellow-green^{1,2}. They possess considerable interest, for light must filter through them to enter the sensitive cone outer limbs, and they may serve, therefore, as a mechanism for colour vision³.

Kühne and Ayres⁴ effected a crude separation of chicken retinal pigments into three fractions: purplish red "rhodophane", golden or orange "xanthophane", and yellow-green "chlorophane".

We have crystallized three such pigments from natural extracts. They are carotenoids, and in suitable solvents reproduce closely the colours of the natural droplets:

1) The purplish red pigment, astacene. Epiphaseic when shaken with benzine and 90 per cent methanol. Insoluble in concentrated caustic potash; precipitates as a red soap on dilution with water. Crystallizes in methanol-acetic acid in thin, curved, purple leaves; from pyridine in fine needles. Crystals soluble in benzine, almost insoluble in methanol, slightly soluble in pyridine. The spectrum consists of a single broad band, maximal at 477 mμ in hexane (Fig. 1a), at 499.5 mμ in pyridine, at 497 mμ in castor oil (used to simulate the retinal oil).

Fig. 1.

2) A golden or orange xanthophyll. Shaken with benzine and 90 per cent methanol, it is epiphaseic and hypophaseic after saponification. This is typical behaviour of xanthophyll esters. Crystals in methanol solution are orange-red in colour, practically insoluble in benzine, readily soluble in methanol. The spectrum possesses three bands, at 1), 449.5 and 478 mμ in hexane (Fig. 1b), and at 2), 463 and 490 mμ in castor oil. This is close to the spectrum of lutein (447.5 and 477.5 mμ in benzine).

3) A yellow or yellow-green hydrocarbon. Epiphaseic when shaken with benzine and 90-95 per cent methanol. Crystals from methanol solution are set in colour, almost completely insoluble in methanol, readily soluble in hexane. The spectrum possesses three sharp maxima, at 418, 440 and 469 mμ in hexane (Fig. 1c), and at 428, 450 and 469 mμ in castor oil. This spectrum lies at much shorter wave-lengths than that of any known carotenoid except sarcinene (415, 440, 469 mμ)⁴.

It seems clear from the appearance of the coneules that one of these pigments predominates in each of them. The fact that one pigment is acidic, one an alcohol and one a hydrocarbon greatly aids its separation *in vitro*. A precisely similar situation

is found in the retina of the turtle, *Olemmys insculpta*⁵. Possibly this chemical differentiation is the basis also of pigment segregation *in vivo*.

Astacene apparently is synthesized by the chicken. We found no trace of it in chicken livers or serum. Though none could be found in the egg yolk, red cone droplets appeared in our chick embryos on the nineteenth day of incubation (37°C.). The hydrocarbon pigment also may be synthesized *in situ*, for it has not been identified either in the egg or in the customary chicken diet.

If the chicken depends upon these pigments for colour discrimination, it should fail to differentiate monochromatic lights between about 600 mμ and 700 mμ, for none of the pigments in castor oil absorbs appreciably in this region. It is significant that the pigeon, which possesses a similar system of cone droplets, is unable to discriminate hue differences between 615 and 700 mμ⁶.

Position of Maximum Optical Sensitivity of Sensitized Photographic Plates

In one of the first papers¹ on the phenomenon of sensitization of photographic plates to the long-wave rays of the spectrum by dyestuffs, Vogel noted that the maximum sensitivity is often shifted by several hundred Angstrom units towards the red in comparison with the maximum absorption of the dyestuffs in solution. The usually accepted explanation² of this phenomenon is that it is due to the displacement of the maximum of absorption of the dyestuff by its adsorption on the silver halide. But on account of the difficulties connected with measuring the absorption by scattering media, this hypothesis has not yet been confirmed experimentally.

POSITIONS OF MAXIMA OPTICAL SENSITIVITY

Fig. 1.

With the aid of the König-Martens spectrophotometer, we have obtained absorption curves of erythrocin and phloxine sensitizers adsorbed on transparent layers of silver bromide sublimated in vacuum. They were prepared by a method analogous to the method of de Boer³ as described in a series of papers by him on the adsorption of dyestuffs on sublimated layers of alkali earth metals.

The general trend of the curves of these two stations is in beautiful agreement with our curve. The magnetic intensity curve from Vienna-Auhof is nearly identical with the curve of the two American stations.

In Fig. 2 the daily mean values of the horizontal intensity are plotted together with the cosmic ray ionization and with the number of triple coincidences as observed by L. Jaeger on the Hafelekarr with two sets of Geiger-Müller counters, consisting each of three counters placed vertically above each other. Here once more the close similarity in the variation of the cosmic ray intensity and the horizontal magnetic force during the magnetic storm is clearly demonstrated.

Fig. 2.

DAILY MEAN VALUES OF COSMIC RAY IONIZATION, OF NUMBER OF COUNTER COINCIDENCES AND OF MAGNETIC HORIZONTAL INTENSITY, APRIL 23 TO MAY 1, 1937. $\circ-\circ-\circ$, COSMIC RAY IONIZATION; $\circ-\circ-\circ$, NUMBER OF COUNTER COINCIDENCES; —, MAGNETIC HORIZONTAL INTENSITY.

We think that Forbush's results taken together with our own results prove: (1) that cosmic ray ionization was influenced all over the earth by the magnetic disturbances between April 24 and 30 of this year and that a decrease of the cosmic ray intensity followed a decrease of the magnetic intensity; (2) that the magnitude of the variations of the cosmic ray intensity during magnetically disturbed days may amount to as much as ± 3 per cent; (3) that these variations occurred simultaneously all over our planet. We agree with Mr. Forbush in concluding that the study of the magnetic storm effects will give valuable information on the energy spectrum of the cosmic radiation.

A detailed analysis of the magnetic effects on cosmic ray ionization during one whole year (1936-37) will be published later in *Terrestrial Magnetism and Atmospheric Electricity*.

Concentration of Mesothorium-I by Duckweed (*Lemna*)

It is characteristic of the waters of the earth's crust—among which we can distinguish more than 550 different mineralogical species—that all these chemically different water-solutions constitute theoretically one and the same natural body—a unique great water-equilibrium of the earth's crust¹. They are in constant close material connexion. This connexion is produced by two physical equilibrium systems common to all natural water-solutions:

Water+water vapours (in contact with gaseous atmospheres).

Water+pellicular water (in contact with solids).

The solid substance of the earth's crust is penetrated by pellicular water-solutions². It is characteristic that there are chemical elements which do not enter into the constitution of these solutions³. Among these elements one, on account of its great geochemical and geological importance, must be studied with the greatest attention, namely, thorium. Two deductions can be made from this characteristic of thorium atoms in the geochemical history of thorium:

(1) In relation to the content of thorium atoms in sea-water⁴: either not thorium atoms, but the products of their disintegration—mesothorium-I, radio-thorium, and thorium-X—are present in sea-water, or the thorium atoms are included in the dispersed solid particles distributed in sea-water.

(2) In relation to the thorium content of living organisms: thorium atoms should not be found in the living organisms, which obtain all their metallic atoms from water-solutions, soil-solutions and surface or underground waters.

To verify the second deduction, researches were carried out by B. Brunowsky and C. Kunasheva in the Biogeochemical Laboratory of the Academy of Sciences, Moscow, which proved its truth. A large quantity of duckweed belonging to two species, *Lemna minor* L. and *Lemna polyrrhiza* L., was collected in 1935 from the Orangery Pond at Peterhof (near Leningrad), and a 200-litre sample of water taken.

The plant mass was divided into two lots. The first lot (30.4 kgm. live weight) was dissolved, and the isotopes of radium and thorium separated in the solution by ammonia. The fraction of the solution containing radium isotopes was examined after two years by way of Tn for its mesothorium content, which proved to be $(10.3 \pm 0.3) \times 10^{-12}$ per cent. A month after the separation, in the fraction containing thorium isotopes, the thorium-X was precipitated by barium sulphate, and the quantity of radio-thorium evaluated by determination of Tn. The radio-thorium content of *Lemna* proved to be exactly such as should have generated in *Lemna* from mesothorium-I during the period of time between the taking of samples and the separation of the isotopes.

In 1935, the second lot of *Lemna*, which had been preserved in an air-dry condition for two years, was dissolved and the Tn content determined. The calculation of the mesothorium-I content of *Lemna* was then made on the basis of the observed ionization

affect, taking into account the possibility of thorium atoms being either absent or present. In the first case, the content was calculated to be 10.2×10^{-15} per cent, and in the second 9.05×10^{-15} per cent. These results, compared with the mesothorium-I content given above for the radium isotope solution, which certainly contained no thorium atoms, led to the conclusion that the thorium content of *Lemna* does not exceed 1 per cent of the quantity in equilibrium with mesothorium I, that is, that *Lemna* does not contain isotopes of thorium.

Analogous tests of the pond water proved the presence in it of 8.25×10^{-17} per cent of mesothorium-I, and not exceeding 20 per cent of the radio-thorium for equilibrium with the mesothorium-I. This suggests that, although isotopes of thorium are present in water, they are not assimilated by *Lemna*. On the other hand, *Lemna* accumulates mesothorium-I and concentrates it a hundredfold as compared with its content in the water. The plant, therefore, assimilates radioactive elements, if present in the nutrient medium, in strict accordance with their chemical properties.

Histological Changes produced by Castration and by Sex Hormones in the Adrenals of Normal and of Castrated Male Rats

In our previous publications¹ we have shown that in male rats after castration the weight of the adrenals increases and that this 'castration hypertrophy' decreases or disappears after injections of androsterone, androstanediol, dehydroandrosterone, testosterone, testosterone propionate, androstanediol and androstenedione. In the present communication the results of histological examination of these adrenals are given.

The occurrence of 'castration hypertrophy' in the adrenals of male rats has been observed previously. The effect of injections of some of the hormones mentioned above has been studied only on the X-zone of castrated mice^{2,3}.

The hypertrophy of the 'castration' adrenal is due to the hypertrophy of the zona fasciculata and reticularis, especially the latter, resulting chiefly from a considerable increase in the size of the cells composing these layers. The lipid content of the outer half of the zona fasciculata is definitely increased while that of the reticularis is decreased.

The 'demarcation zone' lies between the glomerulosa and fasciculata zones, and consists of 1-4 rows of cells, in which lipid granules are normally few or absent; after castration it becomes impregnated with lipid and hence appears to be absent.

The width of the zones and size of the cells return to normal or nearly normal size if sufficiently large doses of sex hormones are injected into castrated

rats. Moreover, some hormones may decrease to below normal both the zones and the size of the cells (androsterone and androstanediol).

Vacuolation, which is slightly increased in the zona fasciculata after castration, is decreased after injections of sex hormones, sometimes in a most striking degree, almost disappearing with high doses of androsterone. Testosterone presents a special case; small doses decrease vacuolation, but after high doses (1400 γ) it appears again.

Most doses and hormones investigated produced in all zones, in some cases excluding the glomerulosa, a partial, sometimes nearly complete, disappearance of lipid granules. The discrepancy between the very pronounced vacuolation and greatly decreased number of lipid granules, as shown by Sharlach R staining, was most striking after injections of 1400 γ of testosterone, and somewhat less so with testosterone propionate.

The demarcation zone, apparently absent in castrated animals, appeared again in the injected rats.

The effect of a resting period of nine days after testosterone propionate injections (group 2) was examined by comparing the adrenals of these rats with those of their litter mates killed the day after the last injection (group 1). The following striking difference was noted. In both groups the width of the zones and the size of the cells were reduced to the normal condition. The number of lipid granules, however, was abnormally low in group 1 (usual effect of the injection), but returned to normal in group 2. Thus a complete return to normal was obtained in the adrenals approximately nine days after the last injection.

Injections of testosterone propionate into normal rats greatly decreased both the number of lipid granules in the cortex (especially with 1500 γ) and the vacuolation of the fasciculata cells, and caused an increase in the number of faintly stained nuclei with a poor chromatin network.

Prevention of Assimilation in Respiring Cells

UNTIL recently it was generally assumed that so-called 'resting' cells, suspended in a buffer solution in the presence of a nitrogen-free substrate, could be employed in studying respiration separately from other metabolic processes. Some doubt as to the validity of this assumption is suggested by the studies of Cook and Stephenson¹, which show that the oxygen consumed during the oxidation of glucose, lactate or acetate by *Bact. coli* amounts to only from two thirds to three fourths of that required for complete oxidation.

Barker² advanced considerable evidence that this incomplete oxidation may be due to an oxidative assimilation, which in the case of the oxidation of acetate by the colourless alga *Prototheca Zopfii* may be represented as

Barker also reported that the amount of carbon assimilated varies with the nature of the substrate. Giesberger² also observed this phenomenon with different species of *Spirillum* and showed, moreover, that the amount of carbon assimilated from a given substrate varies with the different species.

The fact that this intimate relation between respiration and assimilation is encountered in such widely different groups of organisms makes it probable that the phenomenon is of a quite general nature. It seemed, therefore, of importance to investigate whether respiration and assimilation are indeed intimately associated in one reaction chain as suggested by the equations advanced by Barker and Giesberger, or whether it is possible to block one process and not the other.

In the course of investigations (Warburg technique) on the oxidative metabolism of washed suspensions of *Pseudomonas calco-acetica* Beijerinck in phosphate buffer of pH 7.1, it was observed that the oxygen consumed during the oxidation of acetate or of butyrate amounted to only approximately three fourths of that required for complete oxidation.

It has now been observed that suitable concentrations of sodium azide ($M/800$) or 2:4-dinitrophenol ($M/4000$) block the assimilatory process and bring about a complete oxidation of the substrates, the rate of respiration being in general only slightly decreased. Higher concentrations of the poisons markedly reduced the rate of respiration also.

In the case of acetate this change in metabolism is not accompanied by any change in the respiratory quotient, since in the absence of the poison its value is also approximately 1.0, the conversion of the acetate apparently proceeding according to the equation

The oxidation of butyrate, however, presents another picture, as under normal conditions the respiratory quotient was approximately 0.68, suggesting that the reaction may be represented as

In the presence of the azide or dinitrophenol the observed respiratory quotient was 0.8, the value characteristic of the complete oxidation of butyrate. The oxidation of acetate by *Bact. coli* proceeds in a manner similar to that described for *Ps. calco-acetica*, and assimilation is also blocked by the same poisons. It was observed that $M/4000$ dinitrophenol tended to stimulate respiration to a slight extent while at the same time the oxidation proceeded to completion.

The observations suggest that it is indeed possible to block the assimilatory process in non-proliferating organisms by the addition of critical concentrations of certain chemical agents, thus permitting the oxidation of a given substrate to proceed to completion at an almost normal rate. These observations also suggest that the so-called 'slimming' agents such as 2:4-dinitrophenol may exert their weight-reducing action in man by a suppression of assimilation, rather than simply by their stimulatory effect on respiration.

Full details will soon be published elsewhere.

Nutritional Value of Some Indian Diets

MCCARRISON¹ has pointed out the great superiority of northern Indian diets as compared with those consumed in the east and south of India. It appeared to us to be of interest to compare the northern Indian well-to-do and poor Hindu diets, the ingredients of which he has listed², by feeding them to rats.

The diets were found to contain calcium and phosphorus in the following amounts:

TABLE 1.

	Ca. (per cent)	P (per cent)	Ca. : P ratio
Northern Indian	0.17	0.23	0.52
	0.18	0.27	0.40
Well-to-do Hindu	0.09	0.22	0.42
	0.09	0.21	0.43
Poor Hindu	0.018	0.06	0.23
	0.021	0.11	0.20

It will be noted that all three diets are low in Ca and P, and especially the poor Hindu diet, which has a rachitogenic Ca : P ratio.

Groups of 8 rats were fed on these diets, group A being fed on the northern Indian diet and B and C on the well-to-do and poor Hindu diets respectively. The diets were fed uncooked. The mortality in groups A and B was nil, but of those in group C, six died of pneumonia and none survived more than 105 days. The rate of growth of group A was about 2 gm./day, of group B about 1.4 gm./day and of group C about 0.9 gm./day. In the case of rats on stock diet, this is about 2.7 gm./day.

Rats were killed at intervals and the ash content determined in the lower incisors, one femur, tibia and fibula. The figures for bone ash at 105 days of age, which are typical of all the values obtained, are given below, together with figures from control rats on the Rowett Institute stock diet.

TABLE 2.

Age (days)	ASH CONTENT OF BONES.			Control
	A	B	C	
105	50.8	42.0	31.0	63.3

These values show that calcification was impaired in all three groups, compared with the controls, and especially so in group C. Changes in the same direction, but of smaller degree, were found in the teeth. This is in accordance with the well-known fact that the composition of the teeth is not so readily altered by dietary means as is that of the bones.

The width of the predentin in the upper incisor teeth was measured, the following average values being obtained:

A	B	C	Control
25 μ	21 μ	51 μ	18 μ

The normal value is about 18 μ and is increased when calcification is poor; these values therefore indicate that the calcification of the teeth was impaired in all three groups compared with the controls, and especially so in group C. In groups A and B, the incidence of interglobular dentin was higher than normal. In group C, the dentin contained a great many interglobular spaces and also showed a high degree of stratification; the predentin in this group had many vascular inclusions.

In breeding, all three groups were definitely inferior to normal rats on stock diet. Group C did not breed at all. Group A mated at the normal time, but the litter weights, weaning weights and number of young surviving to weaning were low. Group B showed the same poor reproductive performance and in addition the mating date was much retarded.

Although the number of rats used was small, the results confirm McCarrison's finding that the northern Indian diet is superior to both the Hindu diets. The poor Hindu diet is defective on all points; and it is of interest to note that, judged by modern standards, the northern Indian diet is further capable of improvement.

Solubility of Silica Dusts

THE industrial disease of silicosis has been postulated to have a relation to the dissolution of particles of mineral silicates in the lung. Whether this 'solubility theory' of silicosis be true, considerable interest is attached to the production of soluble silica from finely divided mineral dusts. The amount of silicic acid which a mineral form of silica will yield in solution is exceedingly small when it is present as crystals or as coarse fragments. But if it be reduced to a particle size of the order of the dust in the air (that is, < 1 to 10 microns) then the dissolution rate becomes appreciable.

In a recent paper, Emmons and Wilcox¹ gave figures for the silica dissolved from a number of mineral silicates. The method adopted in the study of the dissolution of these dusts is open to grave criticism. For the separation of the liquid phase (blood serum) from the solid (the powdered mineral) these workers relied on centrifugalization at 3,500 r.p.m. for fifteen minutes: the dusts having been exposed to the serum for two months at 37°. The total amount of silica in the supernatant fluid was determined by ashing an aliquot, following by gravimetric analysis.

The rate of sedimentation of particles depends on their shape; a roughly spherical particle tends to settle more quickly than a fibrous particle, even though the particles be of approximately the same size. Centrifugalization at the modest speed of 3,500 r.p.m. for fifteen minutes will not completely remove fine particles of the size (1-10 μ) used by Emmons and Wilcox—particularly from a viscous fluid like blood serum; and the extent to which they are removed will depend on the particle shape. It is notable that the figures showing the greatest percentage of silica dissolved are for fibrous minerals. Thus, in the results for human blood serum, sericite and asbestos give a much greater apparent 'solubility' than opal, quartz or cristobalite. In some cases, for example, that of quartz, which sediments rapidly, the results may approximate to the true solubility figure, but in others where the rate of sedimentation is low they are probably greatly in excess. If the results are expressed in terms of the mgm. SiO₂ contained in 100 c.c. of solution, then figures of 5.0 and 3.8 are found for quartz, a solubility figure in reasonable agreement with other published data. But the figures found for sericite, namely, 14.3 and 9.2, are very much higher than other recorded results. It is suggested that these results do not, in fact, represent the silicic acid in solution; they represent

the total amount of silica left in suspension, plus what small amount may be in solution. Only by high-speed centrifugalization, for example, 15,000 r.p.m. for forty-five minutes, is it possible completely to remove these particles from suspension.

A true measure of the amount of silicic acid which has gone into solution from a powdered mineral can be gained in two ways. The suspended material can be completely separated from the soluble, and the total silica in the separated liquid determined by gravimetric analysis; or secondly, advantage can be taken of the fact that in certain chemical reactions only the silica present as silicic acid will take part. Such a reaction is represented by the well-known formation of silico-molybdic acid, a substance which imparts an intense yellow colour to its aqueous solution even when it is present only in minute amount.

Powdered amorphous or crystalline silica when freshly suspended in water gives no colour on the addition of molybdic acid, but does so after it has stood in contact with the water for some hours, that is, when some of the silica has passed into solution as silicic acid. The measurement of the intensity of the yellow colour (or of the blue colour in a refinement of the method where the silico-molybdic acid is reduced to a blue complex) furnishes a means by which the amount of silicic acid in solution can be estimated, the maximum part of the suspended material having been removed by filtration through very fine paper. Results obtained by this type of procedure probably show fairly accurately the actual soluble silica content of the solution. Such results will vary, of course, with the concentration of the dust and its degree of fineness, as well as with the

Acidosis and Off-flavoured Milk

VETERINARIANS have assisted in explaining one cause of taint of milk when showing that in cases of acidosis the body fluids, including the milk, contain acetone and acetone-bodies. It was stated that the milk would react to Rothera's test¹.

As a result of recent experiences with samples of milk from cows suffering from acidosis, we can commend this very simple test to the dairy industry (it appears at present to be quite unknown) as a rapid and certain means of diagnosis, offering an explanation of many cases where the milk is mildly, but to a skilled palate, definitely of abnormal flavour even at the time of milking. Such cases have hitherto been somewhat vaguely ascribed to 'indigestion'.

Furthermore, we find that for more accurate work, quantitative estimations may be made by the method of Van Slyke². Several samples from cows giving tainted milk have been so examined, and in addition more than 98 per cent recovery has been obtained from samples of milk to which small amounts of acetone have been added.

Points from Foregoing Letters

COMPARISON of the change in the intensity of cosmic rays for a period of nine days (April 23–May 1, 1937) during a magnetic storm at Innsbruck (Austria), Cheltenham (Maryland, U.S.A.) and Huanacayo (Peru), shows very good agreement in the general trend, according to Prof. V. F. Hees and A. Demmel-mair. There is also a close parallelism to the change in the horizontal component of the earth's magnetic field during this period, and the authors conclude that cosmic ray ionization was influenced simultaneously all over the earth by the magnetic disturbances, and that the study of the magnetic storm effects will give valuable information on the distribution of energy in the spectrum of the cosmic radiation.

Chemical analysis of a sample of duckweed (*Lemna*) shows, according to Prof. W. I. Vernadsky, B. K. Brunowsky and C. G. Kunaheva, that the plant contains about one hundred times more mesothorium-I (10×10^{-15} per cent) than the water in which it grows (Orangery Pond, near Leningrad). On the other hand, although isotopes of thorium are present in water, they are not assimilated by the duckweed. The authors conclude that the plant assimilates radioactive elements in strict accordance with their chemical properties.

K. Hall and Dr. V. Korenchevsky find that the increase in the size of the adrenals in castrated rats is due to increase in the width of certain zones (fascioulata and reticularis) resulting chiefly from an increase in the size of the cells. They return to normal if sufficiently large doses of sex hormones (androsterone, testosterone, etc.) are administered. In a similar way, the large numbers of lipid granules which invade the 'demarcation zone' upon castration may be made to disappear.

From the effect of critical concentrations of sodium azide or 2:4-dinitrophenol on the rate and extent of oxidation of acetate or butyrate by bacteria, Dr. C. E. Clifton deduces that these agents block the assimilatory process observed in association with the respiration of widely different non-proliferating cells under normal conditions. This blocking of the assimilatory process is accompanied by a complete oxidation of the substrate, at an approximately normal rate. He suggests that the weight-reducing action of the dinitrophenols in man may be due in part to a suppression of assimilatory processes.

By feeding rats with diets as used in Northern India, by well-to-do and by poor Hindus respectively, and observing the effects upon the teeth, the fertility and the health of the young, D. N. Mullick and Dr. J. T. Irving find that the Northern Indian diet is superior to both Hindu diets and that the poor Hindu diet is seriously defective as shown by both chemical and biological tests.

A table giving the amount of silica dissolved by a 1 per cent sodium bicarbonate solution and by acetic fluid from silica dusts (quartz, sericite) after various periods of time, is given by Dr. E. J. King. The author states that many of the values reported by Emmons and Wilcox for the solubility of finely powdered silicates are too high, because their method does not eliminate completely the fine particles in suspension.

The presence of a minute hole in a polished glass disk enables it to make 'optical' contact with another polished plate by application of slight pressure at a single point, according to Dr. J. W. French. The contact spreads spontaneously, due apparently to the surface tension effect of a grease-like film (less than one millionth of an inch thick) present at the glass surface.

D. Porret and Dr. E. Rabinowitch find that the reversible bleaching of chlorophyll by light is proportional to the square root of the light intensity. Formic acid causes a considerable increase in the reversible bleaching, while oxygen and ferrous chloride suppress it.

The interference in the two segments of the X-chromosome of *Drosophila melanogaster* is characterized by Prof. K. de Kőrösy by two constants, the *transitive* interference from one segment on the other by a third. The average deviation between the calculated and observed data is 0.6 per cent, with a maximum of 1.8 per cent.

A table showing the Raman spectra of various heavy-hydrogen substituted ethylenes is given by Prof. M. de Hemptinne, J. Jungers and Dr. J. Delfosse. Some of the lines were determined by using pure compounds (C_2D_4 , $C_2H_3D_3$) and the remainder from a mixed sample. The authors find a slight discrepancy between the experimental results and the theoretical calculations carried out by Manneback and Verleisen.

where $\bar{f}$ is the whole map-distance between the two intervals, $\bar{f}_r$ is the map-distance on the right segment from the boundary; $a = 0.257 = a_s$, $b = 0.559$ (Fig. 2). The limits of the validity of this equation can be discussed only when suitable experimental data are available.

Fig. 2.

TRANSITIVE INTERFERENCE. ABSCISSE: PRIMARY MAP OF THE RIGHT SEGMENT; 0 POINT=MIDDLE OF THE INTERVAL OF C.

The three constants a_s , a_r , b make it possible to compute from six f -values between neighbour genes, which stand for the six observed f -values—that is, from the loci of the seven genes on the primary map—all 21 f -values, the average deviation being 0.6 per cent with a maximum of 1.8 per cent (Table 1).

TABLE 1. f -VALUES OF THE "XPER" EXPERIMENT.

Raman Spectra of Deuteroethylenes

THE various deuteroethylenes can be obtained by exchange from ethylenes and deuterium oxide on a nickel catalyst. 15 gm. of heavy water (D_2O) and 6 litres of ethylenes (N.T.P.) yielded after an exchange of several days at $150^\circ C$. a mixture of ethylenes containing about 50 per cent of the hydrogen as deuterium. The Raman spectrum of this substance was taken. In order to identify the lines and attribute them unambiguously to the different compounds, some of the deuteroethylenes have been prepared in a pure state. The ethylene C_2D_4 was obtained in the following way:

The compound so obtained contained about 10 per cent C_2D_3H ; its D content was thus about 97 per cent of the total hydrogen. The *cis* and *trans* di-deuteroethylenes were obtained in an analogous way starting from C_2D_4 and HBr . The comparison of the various spectra permits the classification of the lines as shown in the accompanying table:

C_2H_4	C_2D_4	C_2H_3D	C_2HD_3	$C_2H_2D_2$ <i>cis</i> and <i>trans</i>	$C_2H_2D_2$ <i>asym.</i>

(cm.⁻¹).

There is a slight discrepancy between the experimental results and the theoretical calculations carried out by Manneback and Verleisen. The potential function proposed by these authors has thus to be revised; this revision has been started by Manneback and his co-workers. The comparison of the first three lines (S_1 lines) of C_2H_4 and C_2D_4 gives a measure of the anharmonicity correction. The ratio of the product of these three frequencies should be 2. Deviations from this value are to be ascribed to the anharmonicity of the vibration. This constant was not taken into account in the earlier calculations; in fact, we find the value:

$$\frac{1621 \times 3007 \times 1341}{1515 \times 2251 \times 981} = 1.954.$$

The results indicate that it is of the order of magnitude of 2 per cent. Several lines not given in the table could be detected in the spectrum of the di-deuteroethylenes. It has not been possible to ascribe them unambiguously. Further work is in progress.

Research Items

Blood-Brotherhood in Dahomey

M. PAUL HAZOUMÉ, in the course of an account of the blood-pact in Dahomey (*Trav. et Mem. Inst. d'Ethnol., Paris*, 25), has essayed a critical analysis of the practices and beliefs with which it is bound up. While religious practices and beliefs hold first place in the institutions of Dahomey, the blood-pact has a profound effect on the formation of character in the individual. It is this which has created their spirit of solidarity and at the same time is responsible for their reserve towards strangers. Those who are parties to such a pact are aware that although it does not create the deep-seated affections, which are attributed to the action of certain mysterious philtres, it does give rise to a feeling of unlimited confidence, because those who are bound by this tie are aware that their 'brothers' will never betray them with impunity. In other words, the chastisement which is the sanction of a violated oath will keep those who have subscribed to the pact within the paths of duty it has laid down. In the mutual drinking of blood they have taken on a mutual obligation of affection, confidence and help which overrides even the claims of blood relationship. The assistance due extends from the erection of huts and work in the fields to sacrifice of life itself. It involves the taking up of arms on behalf of blood-brothers against injustice and treachery. It is also a protection against robbery; and kings found in it an instrument of power for personal or political objects, disregarding rank and allying to themselves any who might prove useful to their purposes, including experts in magic and spies. On the other hand, no one was allowed to exploit this relation with the monarch for personal gain or social advancement. For long the pact had none but noble objects; but unfortunately it was perverted to evil ends and became an instrument of crime. Originally it was confined to adult males. Now it is a means of assuring the fidelity of married couples, and thieves have resorted to it to join to themselves women, who assist in their nefarious practices by entering into friendly relations with those whom it is intended to rob.

Pain Nerves

WHEN a sharp or a hot object is applied momentarily to the toe, two bursts of pain are felt, the second following the first by an interval of nearly two seconds. T. Lewis and E. E. Pochin (*Clin. Sci.*, 3, 67; 1937) show that this double response depends on the transmission of pain-sense by two sets of nerve fibres having widely differing rates of conduction. They point out that if a pain stimulus is applied at different points on a limb, the interval between the two sensations lengthens as the periphery of the limb is reached. It has been shown by others in the experimental animal that asphyxia interrupts conduction in the fast before the slow fibres; cocaine, on the other hand, paralyses the slow fibres before the fast. Lewis and Pochin show that in man asphyxia abolishes the immediate but not the delayed response to pain, while cocaine abolishes the second response before the first.

Pharmacology of Tetramethylammonium

TETRAMETHYLAMMONIUM has various actions of pharmacological interest. A. J. Clark and J. Raventos (*Quart. J. Exp. Physiol.*, 28, 361-392; 1937) have studied some of these actions and compared them with those of substances formed from it by altering some of the chemical groups in the molecule. The actions studied may be classified as muscarine actions (contraction of rat's intestine and inhibition of frog's heart), nicotine actions (contraction of leech muscle), atropine actions (inhibiting muscarine actions) and curare actions (inhibition of neuro-muscular conduction in voluntary muscle, which may be essentially an inhibition of nicotine actions). The action of drugs on the frog's rectus abdominis is apparently intermediate between these main types. Replacement of one methyl group by a straight-chain alkyl group of increasing length first increases the muscarine activity and then leads to the appearance of the opposed atropine activity. This is explained on a theory, to which Gaddum has given mathematical expression, according to which the antagonistic drugs combine with the same chemical groups in the tissues as the active drugs and block them up. The results generally agree quantitatively with this theory. These changes in the molecule do not much affect nicotine actions or curare actions. Replacement of all four methyls by ethyl, propyl or butyl abolishes muscarine actions and increases atropine actions. Replacement of methyl groups by increasing numbers of ethyl groups diminishes all actions except that on the leech, which is first diminished and then increased. The introduction of a phenyl group has an effect like that of the introduction of three carbon atoms in a straight chain.

Speed of Flight of Birds

IN a Circular (No. 428) published by the U.S. Department of Agriculture, May Thacher Cooke has collected all the records of the speed of flight of North American species of birds and of a few European species which have occurred in North America and are closely related to North American species for which no records are available. There are also included a few running speeds which show that for short distances quail may cover the ground at 12-15 miles per hour, the road-runner at 10-20 miles, while for the emu Le Souëff's record is quoted of a bird driven for 10 miles at a speed of 31 m.p.h. Of the flight records it must be said that many are unsatisfactory, since it would appear that in many cases no allowance has been made for favouring or adverse wind. Thus presumably arises the anomaly of one observation from a moving train giving a speed of 25 m.p.h. for the crow, while another gives 60 m.p.h., and an automobile observation 25-32 m.p.h. But the author seems to consider that wind has no great influence upon the flight of birds, and in support she quotes the case of brown pelicans timed along the beach at El Pismo: 14 m.p.h. with practically no wind, 16 m.p.h. with half a gale blowing half rear, 22 m.p.h. with wind velocity of 50 m.p.h. in the same direction. The old statement

is repeated that birds prefer a side or even a head wind to a following wind. Until observers realize that the speed of a bird's movement in relation to the ground has no biological meaning until corrections have been made for the influence of the wind, these faulty records will continue to accumulate.

Migrations of Salmon

FURTHER evidence of the actual movements of salmon in the sea is given by W. J. M. Menzies (Fisheries, Scotland, Salmon Fish., 1937, No. 1) from the recapture of marked fish. The main experiment was carried out in 1936 at Loch Inchard, twelve miles south of Cape Wrath, a spot chosen as the result of knowledge obtained from experiments in other localities in previous years. Of 1,255 fish marked, 11.7 per cent have been recaptured, at various places so far away as 145 miles to the south and 410 miles east, and south to the Yorkshire coast and even in Norway. The suggestion is put forward that these fish had collected at Loch Inchard from some feeding ground to the west or north, and thence migrated purposively to the positions at which they were recaptured. This view is supported in a remarkable manner by scale examination. As a result of extensive investigations in recent years, the type of parr growth, which differs from river to river, is now known for a large number of rivers. With one exception, all these recaptured salmon showed on their scales the parr growth typical of that of fish from the rivers in which they were recaptured. This seems rather conclusive evidence that the fish were proceeding via Loch Inchard on a definite migration to their own particular rivers.

Hemipterous Insects of the Family Peloridiidae

THIS small and scarce family of hemipterous insects was for a number of years only known from two examples from the southern extremity of South America. In 1920 a further example was discovered in New Zealand, and in 1924 a nymph was found on Lord Howe Island. Later, examples turned up in Australia and in 1933 a number of specimens were found in that country by Mr. I. W. Helmsing, which have enabled a more detailed study of the family to be made. In the *Annals and Magazine of Natural History* of May, 1937, Messrs. Helmsing and W. E. China discuss the Australian species, *Hemiodocous vitichi*. The favourite habitat for this species appears to be among moss in forests of Antarctic beech (*Nothofagus moorei*). The few known examples of the family were formerly placed in the Heteroptera, but it is now agreed that its affinities are with the sub-order Homoptera. These authors conclude that the establishment of a separate new suborder for the Peloridiidae is not justified, and that the group belongs to a new series in the suborder Homoptera for which the name Coleorrhyncha was given by Myers and China in 1929. The Peloridiidae are evidently a very primitive and generalized family associated with primitive vegetation (mosses), and it is concluded that its members may well have been descended in an almost direct line from protohemipterous ancestors.

Colour of Hydrangea Flowers

It would perhaps be difficult to say whether pink or blue hydrangea blooms are most popular for floral decoration, but the reliable production of blue-coloured flowers has long been a horticultural desideratum. Mr. E. M. Chenery has made an exact

study of this question, and his findings have recently been published (*J. Roy. Hort. Soc.*, 62, Pt. 7, 304-320, July 1937). The paper considers the problem from historical and horticultural points of view, and also compares the influence of soil conditions with the physiology of the plant. From all sources of evidence, aluminium seems to be the element the presence of which induces a blue colour in the flowers, and not iron, as was at one time supposed. Analyses of blue and pink sterile flowers or petaloid sepals showed that aluminium was always greatly in excess of iron when the blue colour appeared. The anthocyanin from pink flowers would, however, form a blue delphinidin complex with both iron and aluminium ions.

Dipterocarpaceae of the Eastern Tropics

IN Forest Products Research Records No. 16 (Timber Series No. 5. H.M. Stationary Office, 1937), Mr. S. H. Clarke, under the title "Gurjun, Apitong, Keruing, Kapur and allied Timbers", deals with a group of timbers from the eastern tropics which has in recent years become increasingly important to the wood industries of Great Britain. From a commercial point of view, the family Dipterocarpaceae is the most important group of timber trees in the eastern tropics—occupying a more or less similar position in Burma, the Malay Peninsula, Sumatra, Borneo and the Philippine Islands to that occupied by the soft woods in the great forests of Canada and the U.S.S.R.; the dipterocarps, however, rarely occur in pure forests, yet they yield a larger volume of timber than all the other species occurring in mixture with them. The family comprises nineteen genera and some 880 species. The *Shorea* timbers are the lightest; *Dipterocarpus* and *Dryobalanops* moderately heavy, and, though not very durable under exposed conditions in the tropics, are well suited for constructional and other purposes in the temperate climates. The hardest woods of the family come into the genera *Vatica*, *Hopea* and *Balanocarpus*. These are too heavy and hard to be of use for general purposes in Great Britain, though they form the chief constructional timbers in the countries producing them. The chief exploited species of the family are magnificent trees with a bole running up to 80 ft. or more without a branch, and a diameter which may reach 5 ft. Resin or gum occurs in some of the species. The pamphlet gives a general classification of the timbers in a tabular statement showing the countries of origin and the chief species of the principal genera *Dipterocarpus*, *Dryobalanops*, *Shorea*, *Hopea*, *Vatica* and *Balanocarpus*.

Erosion Surfaces of Cornwall

MARINE action has clearly played a great part in shaping the physiographical features of Cornwall. Platforms at 1,000, 800 and 400 ft. have been mentioned and a 200-ft. level has been suggested. Mr. W. G. V. Balchin, in an article in the *Geographical Journal* of July, gives the result of his investigations in north Cornwall, and tries to date the platforms which he has recognized, pointing out that the present physiography had its origin, for the major part, in the dissection of a series of platforms. The erosion surfaces are generally separated by a bluff which when not of structural origin is probably due to marine action. In the area investigated the highest platform, notable on Bodmin Moor, is at 1,000 ft. and is probably late Miocene. Below that is a minor platform at 850-920 ft., and again one at heights

varying from 600 ft. to 820 ft. conspicuous near Camel-ford and probably later Miocene. The best preserved platform is at 300–430 ft., well seen between Boscastle and Tregardock and of Pliocene origin. Finally comes a surface at 240–285 ft. of late Pliocene age, noticeable in many of the flat-topped hills of the Padstow district.

Magmatic Differentiation

At the Tercenary Conference at Harvard University last September, Dr. C. N. Fenner summarized some of the major difficulties that are encountered in attempting to explain all the phenomena of differentiation of igneous magmas by a single process. The paper is now published in the *Journal of Geology* (158–168; 1937). It is pointed out that the Goose Creek diabase contains both quartzo-felspathic micropegmatite and very basic macropegmatite. Unless, therefore, liquid immiscibility be granted, both cannot represent residual magmas, since this would mean that the magma was differentiating simultaneously in two very different directions. The official interpretation of the Glen More ring-dyke (Mull) as an example of differentiation into gabbro and granophyre is shown to violate fundamental principles of chemistry and dynamics. Granitic rocks from the Bushveld Complex are similar to those which have been claimed as products of crystal fractionation from basic magma, and yet they have been demonstrably produced by the granitization of sedimentary quartzites. For many years, a controversy has been carried on as to whether, or to what extent, magmas are capable of assimilating solid rock. It has been repeatedly stated that the great obstacle to assimilation is the supposed inadequacy of the heat supply. Fenner describes phenomena from Alaska and the Yellowstone Park which irrefutably prove that "rhyolite magma was able to do things that the theory of crystal fractionation declares impossible". The facts show that rhyolite magma, so far from being the coolest of the evolution series, possesses great and hitherto unsuspected reserves of latent energy. Fenner insists on the necessity for giving such facts more adequate consideration. So did Goodchild more than thirty years ago, in a paper that was quietly ignored (*Trans. Roy. Soc. Edin.*, 202; 1904), so strong was the prejudice in favour of theory when theory and observation were in conflict. Fortunately, that prejudice is at last crumbling away, as the irrepressible facts become more widely known.

Retardation of Chemical Reactions

The reaction between potassium permanganate and hydrogen peroxide is retarded by hydrogen peroxide in fairly concentrated solution, an effect which has been attributed to the formation of inactive H_2O_2 molecules at higher concentrations. K. C. Bailey and G. T. Taylor (*J. Chem. Soc.*, 994; 1937) have re-investigated the reaction, measuring the extent of decomposition with a photo-electric colorimeter, the effects of stirring and of traces of manganous ions being particularly controlled. With initial permanganate and sulphuric acid concentrations constant, the reaction velocity reaches a maximum at $(H_2O_2) = 0.005$ equiv./l., falls to a minimum at $(H_2O_2) = 0.16$, and rises slowly at higher peroxide concentrations. With initial permanganate and peroxide constant, and the latter at concentration greater than 0.02, the velocity rises to a maximum

with increase of sulphuric acid, falls to a minimum, and then rises again. Manganous ions catalyse the reaction powerfully at peroxide concentrations rising to the maximum velocity concentration but have little effect near the minimum velocity. Other effects were found and a theory covering all the data is not proposed. It is considered that the reduction of MnO_4^- to Mn^{2+} probably takes place in stages, the first perhaps involving the production of MnO_3^- which may be capable of being re-oxidized to MnO_4^- by a molecule of H_2O_2 with sufficient energy. A fair agreement with experiment is obtained by an empirical equation: $v = k_1(H_2O_2)(H_2SO_4)(KMnO_4) / (k_2 + k_3(H_2O_2)^2(H_2SO_4)^2)$, the terms in the denominator representing two types of retardation, the second being the re-oxidation of partly reduced permanganate by active hydrogen peroxide.

Investigation of Porous Structure

An emanation method has recently been described (G. Graue and N. Riehl, *Naturwissenschaften*, 25, 423; 1937) which offers possibilities of examining the porous nature of catalysts and of studying reactions in solid phases. The emanation method of Hahn, first described in 1929, depends on introducing a radioactive element which forms a gaseous emanation on disintegration into the solid. The degree of porosity is indicated by the quantity of emanation which can be detected in the neighbourhood of the solid. This method has the disadvantage that it can only be used for special substances in which the radioactive substance can be included. The method now proposed is to allow the emanation to penetrate the solid from outside, the amount penetrating indicating the porosity. The method has been used to determine the true specific volume of crystalline and precipitated zinc sulphide. The value obtained for the specific volume of crystalline zinc sulphide was the same as that determined by the pycnometer method, but for precipitated zinc sulphide the value obtained by the emanation method was much smaller than that with the pycnometer. It must therefore be assumed that in amorphous (precipitated) zinc sulphide there are pores or fissures of atomic dimensions due to an irregular arrangement of atoms. It is possible that gases penetrate into the interior of solid catalysts not only by means of large pores, but also by inter-atomic pores and clefts due to badly formed lattices.

Recent Sunspot Activity

DATA contained in Nos. 36 and 37 of the Zurich *Bulletin for Character Figures of Solar Phenomena* for the six months October 1936–March 1937 show how considerable has been the sun's activity of late. The mean daily sunspot 'numbers' for each of the six months are, respectively, 89, 115, 123, 133, 128 and 84. The highest value reached in the preceding 11-year cycle was 108 for December 1929; but in the earlier cycle with a maximum in 1917 the value 155 was reached in August of that year. The mean number for the year 1936 was 80.4 as compared with 36.1 for 1935, 8.7 for 1934 and 5.7 for 1933. Since March 1937, activity has remained considerable. Large sunspots crossed the sun's central meridian on April 22.4, April 23.2*, April 24.6*, April 29.6, May 20.8*, May 27.2, June 4.9, June 15.6, June 16.9*, June 21.2, June 27.0 and July 28.6*. Those groups marked with an asterisk exceeded, at maximum development, 1,000 millionths of the sun's hemisphere as given by the Greenwich measures of area.

The Palace of 'Discovery at the Paris International Exhibition, 1937

By Dr. Pierre Biquard

EVERY day thousands of visitors from all parts of the world enter the Palace of Discovery of the Paris International Exhibition. Some go as experts to see how far science lends itself to spectacular demonstration. Others, realizing their lack of knowledge, go to learn. Furthermore, some people, especially the young, go brimful of eager curiosity, hoping to find somewhere in those halls an inspiration which will guide them in the choice of their career.

One thing is certain, no one is disappointed. It is obviously impossible to cover in a brief article the entire field of present-day science, and relate the history of scientific progress up to date. This is merely a brief statement of what has been achieved in the different sections of the Palace of Discovery. The Palace covers an area of 23,000 square metres. All branches of scientific learning are represented, from mathematics and astronomy to medicine and botany.

The greatest efforts have been made to replace by real demonstrations the silent testimony of documents and pictures. In all sections a staff of demonstrators escort the visitors and carry out experiments, though many work automatically and can be set in motion by the public. The magnitude of the undertaking is shown by the single fact that the electrical installation of the Great Palace is on a greater scale than that of a whole district in Paris: ten kilometres of feeders and sixty kilometres of cables were needed, and it is estimated that the cost of the electricity used during the course of the Exhibition will amount to 1,000,000 francs.

In accordance with the views of Auguste Comte, mathematics will be dealt with first. It may be true, as Emile Borel wrote in Paris, 1937, that "only those who have given up their lives to mathematical research know what it is, what are its aims and by what means it attains them"; nevertheless the rooms set apart for mathematics show to all visitors the development of this science from the earliest times and the growing importance that it has acquired in modern developments of physics, chemistry, biology, etc. Certain questions are explained by means of films: in this way visitors are introduced to such subjects as four dimensional space and the laws of similitude, showing that if the dimensions of an individual were increased ten times he would collapse under his own weight. Mathematicians are given the opportunity of working out on the spot at the black-board problems the solutions to which are posted up the following day. It is interesting to see that the eternal riddle of the squaring of the circle occupies a place, and the value of π to 707 places of decimals is exhibited on the surface of a cupola.

The task undertaken by those responsible for the astronomy section has been no small one. They have had to crowd into a few rooms all that is known about a universe so vast that light takes a thousand million years to traverse it. Three models show the structure of portions of space of decreasing sizes: the first represents the galaxy, the diameter of which is of the order of five million light years: the second shows the sun and the twenty-five stars surrounding it in a portion of space through which light travels in

twenty-five years: finally, the third model shows the sun and its attendant planets, that is, a very small space through which light travels in seventeen hours. The northern Milky Way is shown in a photographic enlargement measuring 20 m. $\times$ 4.5 m.; there are also many good photographs of nebulae, of the sun, moon, planets, comets, etc. The movements of the planets in the solar system are reproduced in the great planetarium, and to make them more clearly visible, the rates of their revolutions have been multiplied by 432,000, allowing one revolution of Mercury around the sun to be seen in eighteen seconds. After having examined all that can be seen in space from the earth, the visitor naturally wonders what our world would look like to other beings living on some other planet. An answer to this question is given by a model 70 cm. in diameter which was made as the result of the observations of explorers of the stratosphere.

Physics occupies a favoured position in the Palace of Discovery. In a room dedicated to Galileo are seen the fundamental experiments relating to falling bodies, the oscillations of the pendulum, centrifugal force, the laws of composition of forces. All the foundations of the so-called 'rational' mechanics are there, and it is impossible not to dwell on the scientific progress in physics and astronomy made on this basis up to the time when its application to optics was found to be impossible.

The history of our knowledge concerning light appears in the section devoted to optics. After having thus learnt anew the laws of reflection and refraction, and measured the velocity of the propagation of light, the visitor can watch a series of experiments on interference, diffraction, polarization, interference photography, and will then perhaps be convinced of the truth of the wave theory of light. The photo-electric phenomena which can be examined later will give him food for thought.

Another section is given over to electrostatics. Once again the public may see the production of electric charges by the friction of cat skin and, on the other hand, watch the working of the Van de Graaf electrostatic machine set up under the direction of M. Joliot by MM. Lazard and Savel. This machine can produce sparks of several million volts passing between two spheres of three metres diameter.

The field of oscillations is the subject of another section in which electromagnetic and sound vibrations are studied. Special attention must be directed to the manner in which are exhibited the consequences of the discovery by Pierre and Jacques Curie of the piezo-electric property of quartz; the stabilization of high-frequency emissions, quartz pianos, emission and reception of ultra-sound waves, submarine sounding, etc.

Ampère's experiments and the laws of electrodynamics lead up to the triumphs of electrotechnics. By a parallel procedure, it is possible to follow the progress which, starting with the phenomenon of thermionic emission, has led to the creation of modern radiotechnics.

Some of the most beautiful experiments are shown in a section devoted to the states of matter and the

structure of the atom. Matter is heated, cooled, compressed under several thousand atmospheres, expanded, etc. The experiments shown on fluorescence and phosphorescence are as conclusive as they are beautiful. Last comes what is perhaps the most glorious chapter of modern science, the study of atomic particles and radiations. In this section are reproduced all the experiments which have marked a decisive step forward in the study of electrons, of X-rays and the radiation of radioactive bodies, thus passing from the first Crookes tube to the artificial radio-elements and to the cosmic rays made visible thanks to the Wilson expansion chamber.

Four laboratories have been chosen by the chemists to show the history of their particular branch of science: an alchemist's laboratory, Lavoisier's laboratory, Berthelot's laboratory and finally a modern chemical laboratory. While further on, the 'elements' air, water and fire have a special room reserved for them. A great illuminated chart shows the periodic classification of the elements and an ingenious arrangement demonstrates the structure of all the atoms, from hydrogen to uranium. The principal analyses and syntheses are reproduced before the visitors' eyes, notably the separation of the gases of the air and the synthesis of acetylene in Berthelot's 'electric egg'. With regard to each of the important branches of this science—physical chemistry, inorganic chemistry, organic chemistry, metallurgical chemistry, photochemistry, geochemistry—it is possible to estimate how much the researches of pure science have contributed to the progress of industry (paper making, manufacture of sulphuric acid, preparation of colouring matters, dyeing and printing of materials, etc.).

Biology, as might be expected, shows here a living summary of the work of Pasteur together with an exhibit of the developments of microbiology—discoveries relating to smallpox, intestinal affections, cholera and typhus.

Medicine is divided into: (1) the diseases of nutrition, (2) cardio-vascular pathology, (3) medical physics, and (4) the history of medicine, in which

special stress is laid on the fundamental part played by the discovery of auscultation. Also, for surgery, the considerable progress made in the last ten or twenty years is shown, more especially the influence of discoveries bearing on asepsis and anaesthesia. If anyone wishes to learn more about his own organism, and to know what his qualities are, both good and bad, he may take his place on the seat where the human machine is tested. There, after a series of tests, his biometric ticket will be made out and may prove useful in choosing a profession. If the results are good, he will be all the more surprised when confronted with the sensorial illusions shown in the section of psycho-physiology. Experimental biology demonstrates how living beings react to physical and chemical reagents. Plant physiology and biology are illustrated by dioramas, films and collections. Finally, mention must be made of the section reserved for plant genetics, in which are exhibited the great facts of natural selection, of the formation of new species and of natural or induced changes.

Space will not permit the inclusion of the names of the many scientific men from France and abroad who have collaborated in the preparation of this great Exhibition. One exception must, however, be made in the case of the president, M. Jean Perrin. This Palace is the fruit of his untiring labours, and it is thanks to him also that France will soon possess a permanent Palace of Discovery.

It is only natural that in an exhibition representing the arts and technical sciences in modern life, scientific discovery should have its rightful place as the foundation of all progress. The Palace of Discovery brings this home to the general public and also shows the real beauty of science. Possibly, on leaving, the visitor will realize the truth of these words taken from Henri Poincaré's *"Dernières Pensées"*: "Celui qui aura goûté à la Science, qui aura vu, ne fût-ce que de loin la splendide harmonie des lois naturelles, sera mieux disposé qu'un autre à faire peu de cas de ses petits intérêts égoïstes; il aura un idéal qu'il aimera mieux que lui-même et c'est là le seul terrain sur lequel on puisse bâtir une morale".

A Mesolithic Site in Brittany*

THE Mesolithic site of Tévéc, a rocky islet situated about eighteen hundred metres west of the shores of the peninsula of Quiberon in Brittany, which has been explored by M. and Mme. Péquart, is up to the present the most important station of this period that has been submitted to systematic and complete examination. Incidentally, it may be said, it gains in significance by the fact that examination of human skeletal remains from Tévéc has elicited from MM. Boule and Vallois a detailed analysis of the physical characters of Mesolithic man, so far as known from the remains which have survived, and a comparison of this race or type with those of the Upper Palaeolithic.

The investigations leading to the discovery of the site were undertaken by M. and Mme. Péquart in the hope of throwing light on the domestic and tribal economy of the early inhabitants of Brittany,

which had been neglected by archaeologists owing to their preoccupation with the all-absorbing study of the monuments of the country. For this purpose they were convinced that there was little hope of obtaining undisturbed evidence on the mainland, and consequently directed their investigations to the numerous small islands which lie off the coast of the Morbihan. In 1926 they were attracted by the evidence of a kitchen-midden exposed by marine erosion on this barren rock—it is little more, its dimensions being only four hundred metres in its greatest length and two hundred metres at its greatest breadth, while its elevation over the greater part of its extent is no more than ten metres—and began its excavation in July, 1928. After twenty-one days' excavation they were rewarded by the discovery of the first burial. The work of excavation was continued in 1929 and 1930.

The island is completely barren, and even with the resources of modern civilization the excavating party found difficulty in keeping themselves provisioned

* Tévéc. station-nécropole mésolithique du Morbihan. Par Marthe et Saint-Jost Péquart, M. Boule et H. Vallois. (Archives de l'Institut de paléontologie humaine, Mémoire 18.) Pp. ii+227+10 plates. (Paris: Masson et Cie., 1937.) 220 francs.

during their stay on the island. There is, however, reason to believe that at the period of occupation under investigation the island was joined to the mainland, and the mode of life of the inhabitants was riverine, rather than marine. This view is supported by the character of the charcoal, of which an abundance was found. This is the produce of forest trees. The animal remains are also those of a forest fauna. The inhabitants, however, do not appear to have subsisted to any great extent by either fishing or hunting, and their diet was almost exclusively of shell-fish. There is no supply of fresh water on the island.

It was largely this difficulty of making any prolonged stay on the island that was responsible for the fact that it had not been explored archaeologically. The site was actually first discovered by M. F. Gaillard in 1883, but he was able to do no more than make a few *sondages* on the north-west of the island. This brought to light some fragmentary evidence of a cooking-place and gave an approximation of the extent of the kitchen-midden; but the great antiquity of the site was not appreciated. The present explorers recognized by the quantity of culinary refuse, molluscs, fish and game, the quantity of charcoal and the fragments of bone and stone, as well as of the finished implements of these materials, that they were dealing with a kitchen-midden, while the absence of pottery and polished stone as well as the Tardenoisian character of the industry, indicated a Mesolithic site, or to be more precise a site belonging to a phase of culture corresponding to the post-Axilian Maglemose, Mullerup, or Mùgem.

The station covers a superficial area of about two hundred metres square, though without doubt originally it was much larger. Much of it has disappeared by marine erosion. The archaeological bed runs to a depth of from 0.60 m. to 1 m. and is entirely homogeneous throughout its depth in composition and contents. It is composed of a black earth, heavily loaded with carbon, indurated, but breaking up readily, owing to the mass of organic material, bones and artefacts, it contains. The artefacts are homogeneous in character throughout. The site was, in the words of the authors, "*vierge de tout remaniement*".

A number of hearths and burials were found, constituting in all "18 monuments". The burials were of twenty-three individuals, male and female, adult, adolescent and infant. In several instances infants were found buried with adults, for reasons that are not apparent. It is not invariably the burial of mother and child. In one grave the adult was male. Provision was made for the after-life in the form of implements and ornaments, especially necklaces of shells, placed with the body. There appears to be a ceremonial use of deerhorn, possibly as a mark of a special position in the tribe, which recalls the magical significance of horns in Palaeolithic art, as well as possibly being an anticipation of later belief.

The hearths which were found appear to fall into different categories. They are classified by the authors as domestic hearths, which show heavy and protracted use in the calcining of the stones used, cooking hearths, possibly set up for funerary feasts, and ritual hearths for sacrificial meals, which do not show the same signs of protracted use.

The burials are partly in the soil and partly covered by the kitchen-midden material. They show no signs of orientation. The bodies are disposed in

a sitting position, with the legs forcibly flexed and the back against the wall, or else laid on the back, with head and shoulders raised, and the legs flexed, or sometimes crossed on the stomach.

The station is not in reality rich in industries of either bone or stone. Stone artefacts fall into three categories—small implements of geometric outline, finely and carefully worked, flakes retouched over part or the whole of their outline, and a group of specimens of larger size, bolder flaking, comprising nuclei, scrapers and thick flaked tools of various types, in which the fracture seems crude, rather than purposively directed. The bone objects include handles of deerhorn, polishers, objects of indeterminate use made from the tusk of a boar which may have been for piercing leather, and various points, of which one form, a "stiletto" (though only 15-17 cm. long) appears to be accorded a special position in certain burials. Several objects show a simple attempt at decorative art in the form of engraved parallel diagonal or vertical lines. There is no evidence whatever of anything in the nature of permanent structures for habitation.

This discovery of a Mesolithic habitation-necropolis has for prehistoric studies, and for the study of the Mesolithic in particular, a triple interest. It shows for the first time in the prehistory of Brittany a homogeneous and sealed station in the Morbihan of civilization of a people anterior to the builders of the megaliths, and proves, what had previously been denied, that Brittany was inhabited before the Neolithic age. In regard to French prehistory, Ténac may be regarded as the type station of the French Mesolithic, and in fact it is the first to furnish in abundance for France evidence relating to the fauna, flora and industries of that period, while it is the only station which has yielded such an abundance of material for the study of the physical characters of the peoples of Mesolithic age. Further, it throws a flood of light on their culture and beliefs. Finally, in relation to prehistory in general, it makes an important addition to knowledge of the distribution in Europe of Mesolithic culture and a link between the stations of the north of Europe and the south.

While it is clear that this Mesolithic civilization has no relation with the Neolithic of Brittany, there is no indication of its origin. Like the Mesolithic elsewhere, it shows certain features reminiscent of Palaeolithic culture, and it may be that it is a descendant of a Palaeolithic of Brittany as yet unknown.

The physical characters of the inhabitants of the site may be summarized as follows, although this affords only a very inadequate idea of the carefully detailed examination of the skeletal material which has been made by MM. Boule and Vallois.

From the twenty-three burials, twenty-one skeletons were obtained in such a state of preservation as to afford material for observation and study. In general terms, the subjects were not of an advanced age, and there was none who could be described as elderly. Of two very young individuals a few teeth only were obtained. Of the remaining twenty-one, six were infants and six only were truly adult, five ranging in age between twenty and twenty-five years. The sex was easily determined, as in all but one instance the difference between male and female was strongly marked. Out of fourteen individuals six were male and eight were female. An indeterminate individual was probably male, though a low stature possibly indicates a female.

The head measurements were: length, male, 180–190 mm., female, 170–190.2 mm.; breadth, male, 129–143 mm., female, 133–142 mm.; basi-bregmatic height, male, 128–150 mm., female, 129–142 mm.; capacity, male, 1,561 c.c., female, 1,548 c.c.; cephalic index, male, mean, 74.3, female, 75.1. The skulls show a tendency to vary from a moderate dolichocephaly to mesocephaly, this tendency being more pronounced in the female.

In general character the skull is massive, but without marked prominences, thick, and relatively capacious. In form it is 'beloid'. It is high, especially in the men, and carinated with a pronounced median ridge. The forehead is broad and rounded, the glabella moderately developed. The face is large and low, euryprosopic, and mesognathous to prognathous. The mandibles are robust with a pronounced chin. The dentition is megadont. The teeth are remarkable as showing the first known example of caries, not previously recorded before Neolithic times. The stature is distinctly below medium. The forearm is

relatively long. The lower limbs show marked platymeria, and the tibiae are platynemic. As a type, this population is well evolved.

MM. Boule and Vallois have also, as a basis of comparison, made a detailed survey of all the skeletal material of man surviving from the Mesolithic period. This they classify into five types—the Ofnet brachycephal, the dolichócephalic-mesocephals of Tévies, the Ofnet dolichocephals, the Mugem dolichocephals, and the Natufians of Palestine.

On the whole, the authors are inclined to the view that notwithstanding certain clearly marked differences there is a close resemblance between Tévies man and the Chancelade skull of the Upper Palaeolithic. It is certainly closer than to Cro-Magnon man. Of the three possibilities that the type is new in western Europe, that it is a cross-breed, or that it is a variation from Chancelade which has been produced in the long interval of time which has elapsed between the occurrence of the two types, the authors incline to the last-named.

The Electrotor Smoke and Dust Meter

A RECENT paper by Dr. S. C. Blacktin (*J. Indus. Hygiene and Toxicol.*) describes an instrument he has devised for measuring dust suspended in the air. It is of a new type, and in designing it he has attempted to "avoid extraneous mechanisms or electric batteries which mar convenience and portability". The instrument consists of a hand pump of 100 c.c. capacity which draws air through a number of small nozzles, causing it to impinge upon a disk of celluloid or ebonite which, during the impact of the air, is made to revolve by means of a coarsely screwed rod which engages a nut or suitable projection on a hollow piston rod. The revolution of the disk is said to electrify it by rubbing against insulating material. In operation, a clean disk is inserted in the cap and the pump handle is next withdrawn to its greatest extent, and the cap with its disk screwed into position. The pump handle is next pressed downwards, rotating and electrifying the disk and emptying the pump. The ingress port is now held in the dust or smoke dispersion to be determined and the pump handle is withdrawn to its greatest extent

with a steady pull. The air or gas entering the ingress holes against the electrified disk is said to deposit its particle content. The records obtained appear to be circular rings upon the record disk, and these are examined in the usual way under a suitable microscope.

In the paper the instrument is illustrated and described, but no data are given on its efficiency of operation. The apparatus is very simple and, provided it fulfils the function it is intended for, should be a useful addition to the methods available.

It is not easy to see how the construction described could be very effective in its operation; for example, it appears that the dust deposit takes place upon the surface of the disk which is being rubbed by rotation and electrified. Mechanically speaking, it cannot be easy to ensure a suitable rubbing pressure between the disk and the surface in contact with it, taking into account the clearances required in the bearings of the screw and such like. However, as stated already, no information is given on its actual use.

J. S. OWENS.

Performance of Noise Meters in Terms of the Primary Standard

DURING the past few years considerable progress has been made on the intricate subject of noise measurement and many experimental data are now available. A paper on this subject was read by B. G. Churcher and A. J. King to the Institution of Electrical Engineers early this year.

Since loudness is a sensation and not a physical magnitude, its definition and measurement involve subjective considerations such as the manner in which the sound is heard. Until recently these factors were not specified, and so the various types of portable noise meters in use gave appreciably different

indications for a given noise. The British Standard Institution (B.S.I.) has taken an important step in removing difficulties. It has published an authoritative glossary of acoustical terms and definitions (B.S.S. 661) to which most of the workers in Great Britain will conform. Loudness is defined as, "that subjective quality of a sound which, in general, increases regularly with the intensity within the limits of audibility". A natural loudness scale is one such that when the number of units on the scale is doubled the magnitude of the sensation experienced by normal listeners is doubled also. The expression

"equivalent loudness" has been adopted for the physical intensity level of the reference tone relative to the standard pure tone. The unit of equivalent loudness is the 'phon', which is defined as follows: "The standard tone shall be a plane sinusoidal sound wave train coming from a position directly in front of the observer and having a frequency of 1,000 cycles per sec". It is also stated that the listening must be done by both ears, the standard tone and sound under measurement being heard alternately. If when measured in this way the intensity level is found to be n decibels above the standard tone, the sound is said to have an equivalent loudness of n phons.

Equivalent loudness is defined in terms of the loudness-equality judgment of a hypothetical "normal observer" whose loudness judgment is representative of the average person. A group of persons is therefore selected; the larger and the more representative the group the more closely in all probability the group judgment will approximate to that of the normal observer. Experience shows that good results can be obtained, using mathematical statistical methods, with ten normal observers.

Reproducible noises of physically specified composition are set up by means of a loud-speaker, and their phon values determined in accordance with the definition. The same noises can then be applied to noise meters of any type and the difference between the phon values is the meter error for the type and level of the noise applied.

The measurement of noise is a problem of great and increasing importance in engineering. The authors conclude that the B.S. phon enables a consistent and unifying system of noise measurement to be set up, relevant to the manner in which sounds are normally heard.

The measurement of the frequency, intensity, purity and field distribution of the experimental tones is effected by condenser microphone methods. The analyser has a range of 25–25,000 cycles per second, is continuously adjustable and is highly sensitive. The microphones are calibrated by means of a Rayleigh disk. An ingenious electromagnetic tone generator is described by means of which harmonic noises containing up to ten components of any relative intensity may be set up.

Academy of Sciences, Vienna

ANNUAL MEETING

AT the general meeting of the Academy of Sciences in Vienna, held on June 1, the following officers were elected: *President*: Dr. Oswald Redlich, emeritus professor of history in the University of Vienna; *General Secretary*: Dr. Egon von Schweidler, professor of physics in the University of Vienna; *Secretary of the Philosophical and Historical Section*: Dr. Heinrich Ritter von Srbik, professor of history in the University of Vienna.

The following were elected to membership of the Philosophical and Historical Section: *Active Members*: Dr. Camillo Praschniker, professor of classical archaeology, Dr. Rudolf Egger, professor of Roman antiquities, and Dr. Johannes Mewaldt, professor of classical philology, all of the University of Vienna; *Corresponding Home Members*: Dr. Friedrich Wild, professor of English philology in the University of Vienna, Dr. Franz Martin, director of land administration records in Salzburg, Dr. Alfred von Verdross, professor of international law in the University of Vienna; *Honorary Foreign Member*: Dr. Edward Schröder, emeritus professor of German language and literature in the University of Göttingen; *Corresponding Foreign Members*: Dr. Walter Otto, professor of ancient history in the University of Munich, Dr. Jan Huizinga, professor of history in the University of Leyden, Dr. Friedrich Panzer, professor of German language and literature in the University of Heidelberg, Dr. Theodor Litt, professor of philosophy and pedagogy in the University of Leipzig, Dr. Adolf Grohmann, professor of semitic philology and cultural history of the Orient in the German University of Prague.

The following were elected to membership of the Mathematical and Scientific Section: *Active Mem-*

bers: Dr. Karl Terzaghi, professor of hydraulic engineering in the Technische Hochschule in Vienna, Dr. Theodor Pinter, emeritus professor of zoology in the University of Vienna, Dr. Erwin Kruppa, professor of descriptive geometry in the Technische Hochschule in Vienna, Dr. Leopold Adametz, emeritus professor of animal genetics in the Technische Hochschule of Agriculture in Vienna, Dr. Richard Schumann, professor of geodesy and astronomy in the Technische Hochschule in Vienna; *Corresponding Home Members*: Dr. Josef Weninger, professor of anthropology, Dr. Johann Solch, professor of geography, Dr. Roland Grassberger, professor of hygiene, Dr. Karl Mayrhofer, professor of mathematics, all of the University of Vienna, and Dr. Wilhelm Petrascheck, professor of geology, palaeontology and stratigraphy in the Montani Hochschule in Leoben; *Corresponding Foreign Members*: Dr. Otto Grosser, professor of anatomy in the German University of Prague, Dr. Enrico Fermi, professor of physics in the University of Rome, Dr. Ernst Küster, professor of botany in the University of Gießen, Dr. Herman Nilsson-Ehle, professor of botany in the University of Lund and director of the Plant Breeding Institut in Svalöf.

The following awards were made by the Academy: the Ignaz L. Loebl prize, which this year is awarded for physics, to be divided equally between Dr. Marietta Blau and Dr. Hertha Wambacher for their work on the photographic action of α -rays, proton and neutrons; the Rudolf Wegscheider prize for chemistry to Dr. Otto Brunner for his work on stearins and the vitamins of the eye; the Frit Pregl prize to Oberst Max Haitinger for his work on fluorescence microscopy.

Science News a Century Ago

Dr. Andrew Fyfe on the Voltaic Battery

THE first article in the *London and Edinburgh Philosophical Magazine* of August 1837 was by Dr. Andrew Fyfe and was entitled "On the Use of Sulphate of Copper for exciting Voltaic Electricity and on the Employment of Iron in the Construction of Batteries". Fyfe was aware that sulphate of copper was easily decomposed by zinc, and was induced to try it as the exciting fluid in the galvanic battery; he found it far superior to the acids in common use. He had a trough constructed of copper and sheet-iron, the plates being of the same size and number as those in a zinc battery. When sulphate of copper was used in the batteries, "electrolyzation", he said, "commenced almost the instant the trough was filled, and continued in the same way as when zinc was employed, indeed I could observe little difference as to energy of action and to the time that it continued, with this exception, that in general there was rather less gas evolved in the volta-electro meter". In view of the cheapness of the materials used, he conceived that the iron trough might be used for certain purposes.

Fyfe, who was born on January 18, 1792, and died on December 31, 1861, graduated in medicine in 1814 at Edinburgh. At one time he was assistant to Thomas Charles Hope (1766-1844), the professor of chemistry, and himself lectured privately on that subject. In 1827 he published his "Elements of Chemistry". He was president of the College of Surgeons, Edinburgh, in 1842-43 and in 1844 was appointed to the chair of chemistry at Aberdeen, a post he held until his death.

Science in Parliament

COMMENTING on the approaching opening of the first parliament of the reign of Queen Victoria, the *Mechanics' Magazine* of August 1837 said, "The new parliament will, to all appearance, have a smaller number of scientific members (always few enough) than the last, which, in its turn, had fewer than that which preceded it. Sir George Cayley will have no seat in the first parliament of Queen Victoria, while Mr. Babbage is further off the object of his ambition than ever . . . The principal scientific men who remain there are Mr. Heathcoat, the member for Beverton, well known for his inventions in lace machinery, and the (said-to-be-unsuccessful) steam trough; Mr. Handley, the member for Lincolnshire, whose exertions to introduce steam-machinery in agriculture have been great and long continued; and Mr. Jephson, the member for Marlow, who holds a high reputation in the mechanical world. We believe Mr. Roach, the barrister, better known to fame as the inventor of the patent screw-flx, has not secured a seat on the present occasion, or, of course, he would have been added to the scanty list."

The First French Railway

IN August 1837, the railway between Paris and St. Germain—the first in France—was opened. Writing on August 26, the correspondent of *The Times* said, "Paris has put on her seven-leagued boots, and reached St. Germain in a stride! The chateau of Louis le Grand, and the fine terrace sweeping through the forest until it is lost in distance, have kindly consented to approach the metropolis for the

gratification of the numerous *guides* who inhabit it; and St. Germain, with all its interesting scenery, although, if we are to credit the map, it is twelve good English miles from Paris, is now more accessible than the windmills of Montmartre. This *triomphe merveilleux*, as the Parisians delight to call it, is the work of that grand miracle-monger of the nineteenth century—steam . . . For statistics, it will be sufficient to state that the *material* is composed of 105 vehicles, capable of containing 4,070 persons, and of transporting the entire population of Paris to St. Germain in the course of one fine Sunday. The railway, 4½ leagues in length, passes through a beautiful country, traversing no fewer than eighteen bridges, three of which are across the Seine. . . . There is a tunnel, Batignolles, which is divided into two galleries, being above 400 metres. The construction is very solid, the rails being fifteen times heavier than those upon the Liverpool and Manchester road." An account of the lines was published shortly afterwards in the *Mechanics' Magazine*, in which it was stated the rails were 60 lb. per yard as compared with the 30 lb. per yard of those on the Liverpool and Manchester line. By 1840 there were 265 miles of railways open in France; by 1860 this had increased to 5,865 miles and by 1882 to 17,006 miles.

Societies and Academies

Dublin

Royal Dublin Society, May 25.

Report of the Radium Committee for the year 1936. The total number of millicuries of radon issued during the year was 12,835, the number of cases recorded in the report being 552. The report includes a number of detailed reports by various users of radon supplied by the Society.

M. J. GORMAN: A non-bulbing derivative of yellow-fleshed Swedish turnip. A non-bulbing form described resembles Swedish turnip (*Brassica napus* var. *napobrassica*) in having yellow flesh, buff flowers, and behaving as a biennial. By selfing, successive generations were obtained of rape-like plants quite uniform in appearance and similar to the original.

J. BRENN, J. KRANE and T. J. NOLAN: The chemical constituents of lichens found in Ireland—*Portuscaria concreta*. The main constituent of this lichen is nor-stictic acid $C_{18}H_{18}O_8$. Besides mannitol, it also contains a small amount of a substance crystallizing in yellow needles, m.p. 287° C. This latter substance, $C_{14}H_{14}O_8Cl_4$, contains three hydroxyl groups and is probably a trichlor trihydroxy methyl xanthone. It gives an olive green coloration with ferric chloride.

Cape Town

Royal Society of South Africa, June 16.

J. L. B. SMITH: The South African fishes of the families Sparidae and Denticidae. Sparid and denticid fishes occur in all tropical and temperate seas, and are of very considerable economic and taxonomic significance. In South African waters, there are forty species, many of which are endemic, and some are highly specialized and unlike any from other parts. Some species occur in vast numbers and are among the most important food-fishes of South Africa. Taxonomic relationships of the species have never been fully investigated, and the whole group has stood in need of critical revision, which has now been undertaken. Very considerable changes, both taxonomic and nomenclatorial, are proposed in the present work. Illustrations of all species of which no reliable figure exists have been provided, also photomicrographs of several selected scales of most species.

A. J. H. GOODWIN: Archaeology of the Oakhurst shelter, George: (6) The Wilton deposit. Throughout the uppermost 3 ft. of deposit there is a single cultural continuity present. At 36 in., the culture is a normal Wilton; after this level the typical Wilton stone implements are replaced by shell implements. After 18 in. there is an increase in pebble implements. In the uppermost 9 in. pottery appears. Throughout the whole Wilton period the subsistence basis remains the same, and consists of shell-fish, sea-fish, and animals of modern type.

Cracow

Polish Academy of Science and Letters, May 10.

M. JACOB: A possibility shown by Cesàro of summing developments in series of Hermite polynomials.

J. WEYSENHOF: The metric field and field of gravitation.

A. KANIA: The magnetic declination at Cracow during the period 1914-36. The formula western declination = $3.200^\circ - 0.160^\circ (t - 1925)$, t being expressed in years, obtained by the method of least squares, reproduces the observations, 589 in number, with a mean quadratic error of $\pm 0.093^\circ$.

H. LACHS and W. PIKIELNY: The oxidation of sulphur vapour at low pressures.

G. BIRSTEIN and M. BLUMENTHAL: The kinetics of the phenomenon of crystallization.

B. KAMIEŃSKI: Superficial phenomena and the dissociation constant of weak electrolytes.

E. GORSKI: Researches on the utilization of the optical antipodes of racemic acid by *Aspergillus fumigatus*.

B. SWIDERSKI: The fauna of the Jurassic Klippes in the Czarny Czeremcha basin.

J. WILBURG: The survival, at a temperature of 38°C , of the tissues of the embryo of a fowl after its death.

MMR. I. MIKULSKA: Comparative study on the biology and metamorphosis of the larvae of the genus *Catocala*.

J. MARCINKOWSKI: The hybrids of guinea fowl (*Numida meleagris*) and a domestic cock (*Gallus domesticus*) obtained by artificial impregnation.

H. SZARSKI: The vessels of the thymus of some tail-less batrachians.

S. SKOWBON, Z. WIOŃSKI and S. ZAJACZEK: Observations concerning the result of defect or excess of the thyroid hormone in the maternal organism on thyroid body of the foetus, and notes on the effect of partial extirpation of the parathyroid glands on parturition.

Moscow

Academy of Sciences, (C.R., 14, No. 9; 1937).

L. KANTOROVICH: (1) The moment problem for a finite interval. (2) Some theorems on nearly complete convergence.

K. PRESIDSKIJ: A theorem of Liapounoff.

G. M. KOVALENKO: Influence of carbon tetrachloride vapour on breakdown voltages of air.

D. I. MIRLIS: Kinetics of wetting and linear corrosion of metals in polyphase systems: metal-liquid-liquid, and metal-liquid-gas (2).

V. O. MOCHNAČ and V. S. BAGNIUK: The action of the halogen compounds of arsenic and phosphorus on ethincarboxylic acids (1). Addition reaction of arsenic chloride with tetrolic acid.

V. O. MOCHNAČ and A. I. STOLJAROV: Geometrical isomerism of halogen-substituted ethene acids. (2) Addition of hydrogen bromide to tetrolic acid.

N. S. VOBONITS: The existence of the Upper Triassic in the region of the Bureya River basin.

A. S. SEREBROVSKY: The third variant in the 'triangle method'.

V. I. PATRUŠEV: Inheritance of biochemical characters by animals, and its relation to their growth. (1) Glutathione concentration in the blood and difference in size of breeds of farm animals. (2) The catalase content of the blood of horned cattle and of sheep.

Vienna

Academy of Sciences, June 10.

J. KISSER and K. LOHWAG: Histochemical study of lignified cell walls. The early wood of firs is much more resistant to chemical attack than the late wood, and the radial cell walls of the latter are more resistant than the tangential walls.

O. RIED: Influence of irradiated metal compounds on the growth and development of *Phaseolus vulgaris* L. Copper sulphate and sulphide lose their property of inhibiting growth when irradiated with ultraviolet light. The property of bacon fat of stimulating growth is increased by irradiation, especially in the presence of zinc oxide.

A. MALABOTTI: Action of β -indole-acetic acid on plants (2). Influence of growth-promoting substance on the cotyledons of *Phaseolus vulgaris* L.

J. JURÍČÍK: Action of β -indole-acetic acid on plants (3). Action of heteroauxin on foliage leaves and cotyledons.

L. PORTHEIM: Action of β -indole-acetic acid on plants (4). Studies with buds of *Phaseolus vulgaris* L. The curvatures produced in leaves when drops of heteroauxin are placed on different parts are studied.

E. ROUSCHAL: Velocity of the transpiration current in maqui wood.

A. ERDÉLYI: Theory of confluent hypergeometric functions of several variables.

A. KAILAN and F. HARTEL: Velocity of catalytic hydrogenation of oleic and cinnamic acids.

H. DOSTAL: Kinetics of thermal polycondensation reactions.

H. LACHS and A. I. GROSSMAN: Viscosity of cuprammonium solutions of cellulose.

D. BALABEW and N. KOLAROW: Vapour pressure and the size of drops.

M. MLADENOVIC: Elemic acid from manulemi (9). Dihydroelemolic acid.

K. PREIBRAM: Correction to the paper of I. Leitner "Quantum Yield in the Coloration of Rock Salt by X-, γ - and β -Rays".

O. SCHINDLER: A new species of fish (Characidae) from north-east Paraguay.

June 17.

A. KÖHLER and A. MAROHEIT: Recent volcanic rocks in the Lainzer Tiergarten in Vienna.

P. and E. KRUMHOLZ: Diphenylcarbazone. Pure diphenylcarbazone has been prepared from the substance erroneously referred to by this name in the literature.

P. KRUMHOLZ and H. WATZEK: Autoxidation of diphenylcarbazone. Autoxidation is accelerated by traces of copper. The effect is highly specific and can serve for the quantitative estimation of minute traces (10^{-4} mol/litre) of copper in solution.

K. GRAFF: (1) Estimation of colours of stars in large instruments. (2) Red cloud and distribution of stars round δ , ϵ , ζ Orionis.

BERTA KARLIK and K. PREIBRAM: Fluorescence of divalent rare earths.

W. SALOMON-CALVI: Continuation of the clay line in Asia Minor.

A. ROLLETT: Azocolours (3).

R. SERBAL: Studies of the Raman effect (73). Derivatives of cyclic compounds with three and four atoms in the ring.

J. LÖBERING and K. P. JUNG: Kinetics of polymerized aldehydes.

O. BRUNNER and W. KLEINAU: Material of the retina (5). Isolation of vitamin C from the retina.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.

ASSISTANT CLINICAL PATHOLOGIST in the Preventive Medicine Department Laboratories of the University of Bristol—The Secretary (August 28).

ASSISTANT IN AGRICULTURAL ZOOLOGY in the University of Aberdeen—The Secretary (September 1).

ASSISTANT LECTURER AND DEMONSTRATOR IN ZOOLOGY AND COMPARATIVE ANATOMY in University College, Cardiff—The Registrar (September 8).

ASSISTANTS (grade III) in the Meteorological Office—The Secretary (S.S.A.), Air Ministry, Admiralty House, Kingsway, London, W.O.2 (September 7).

DEMONSTRATOR IN BIOLOGY in the Royal Veterinary College and Hospital, Camden Town, London, N.W.1—The Secretary (September 7).

SECRETARY to the Institution of Civil Engineers—The Chairman of the Selection Committee, Institution of Civil Engineers, Great George Street, Westminster, S.W.1 (November 1).

JUNIOR SCIENTIFIC OFFICER (PHYSICIST) at the Fuel Research Station, Greenwich—The Establishment Officer, Department of Scientific and Industrial Research, 18, Old Queen Street, London S.W.1 (quote J. 37/11).

International Co-operation in Science

THE organization of international co-operation must in the nature of things be very different in different branches of science. Thus in astronomy, where no one country can cover the whole of the heavens or observe the sun continually through the twenty-four hours of the day, progress in many branches of statistical and even observational astronomy must depend on observers working in many countries of the globe on mutually agreed programmes. In geodesy the shape of the earth can only be determined with the highest possible accuracy by the survey of long arcs passing through a number of countries. Meteorology, geography and radio-science similarly present obvious examples where international agreements can alone secure the maximum of beneficial results from separate sets of observations and from instrumental and theoretical developments.

On the other hand, in sciences such as physics, chemistry and the biological sciences, where most developments come from the individual investigator and his team of co-workers, the value of international organization is less obvious, being limited at first sight to such important questions as the definition of standards or agreements on nomenclature. These have become the care of International Unions or International Congresses. The organized Union is to be preferred for such work to the Congress, as its framework is on the whole more suited to the maintenance of permanent committees. Both Unions and Congresses fulfil one further purpose of great value in bringing together periodically for discussion and mutual intercourse fellow-workers from many scattered lands, studying a group of cognate subjects. A similar service on a more limited scale is served by the gatherings of specialists in a given field of work held from time to time at various academic centres.

The International Council of Scientific Unions, heir to the old Association of Academies, serves as a link between the chief scientific bodies of the nations and also as a link between the various International Unions that adhere to it. One of its most useful tasks is to organize committees for the study of problems in which a number of Unions are interested: the Committee on Solar and Terrestrial Relationships examines just such a set of problems; the Unions of Astronomy, of Geodesy and Geophysics and of Radio-Science are all interested in its work and nominate members to serve on it.

The International Council may be said to approach the question of international co-operation from the side of the Unions. Another body, the Organisation Internationale de Co-opération Intellectuelle de la Société des Nations, working through its committee of scientific experts, has had quite another line of approach. It may be said to look at scientific questions from the points of view of those familiar with the problems that daily face the League of Nations. Thus the question of organizing help for scientific bodies of undoubted international value that for financial reasons find themselves unable to continue with their work comes naturally to the Organisation. Or again, the publication of important learned papers in languages not widely diffused in the world—a question of importance to scientific workers but not to them alone—has been studied by the Organisation, and a solution is more likely to be reached by the channels to which it has access than by individual Unions or Congresses or even the International Council. The same is true of the question of unauthorized translations of scientific work, and of the co-ordination of funds available in different countries for special

researches—a co-ordination necessary in order to avoid unnecessary or undesirable overlapping.

After some years of negotiations, the International Council of Scientific Unions and the Organisation Internationale de Co-operation Intellectuelle have come to an agreement to work together in the several tasks which they face—not as one body but as two bodies in close touch with each other. Last month, in Paris, at a joint meeting of the two bodies (see *NATURE*, July 17, p. 121), Prof. Ch. Fabry and Sir Gilbert Murray signed an agreement which lays down the method of co-operation of the two bodies, the respective spheres of action being broadly along the lines indicated above. Purely scientific questions will go to the Council, which will work through its constituent Unions: questions of a primarily international nature will be referred to the Organisation. At a recent meeting of the General Assembly of the International Council a proposal

was made for the appointment of a committee on the relation of science to the life of the community. It was pointed out that in its original form this motion covered a field lying beyond the purview of the Council. In the amended form which was adopted, the work of the Committee, which has now been appointed (see p. 358), was limited to the scientific side of the question. The more political side may be taken up elsewhere, and represents the kind of question that may fall to the Organisation to study.

There remain gaps on both sides. Subjects—geology and mathematics may be mentioned—lie outside the range covered by the Council; countries stand aloof from the League of Nations. Still, the *rapprochement* between the two bodies can but strengthen both and may lead to more active co-operation between them and those other bodies which stay outside, though each is carrying out work of similar purpose in its own branch of science.

Native Science in Southern Sudan

Witchcraft, Oracles and Magic among the Azande

By Dr. E. E. Evans-Pritchard. Pp. xxx + 558 + 34 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 21s. net.

DR. E. E. EVANS-PRITCHARD, already well known in anthropological circles for some penetrating studies of the manners, customs and mental constitution of certain peoples of the Anglo-Egyptian Sudan, has by this book placed himself in the front rank of British anthropologists. Europeans who have visited primitive people have always been attracted by the notions which they think they have found concerning witchcraft, oracles and magic; but most of them have attempted to interpret these notions mainly in the light of their own, or what they consider to be their own, habits of thought. Consequently, these topics have been treated as if their main interest lay in their curiosity, their oddity; and not infrequently they have been taken to indicate that there is some sort of primitive logic exceedingly different from that of the Western world. Dr. Evans-Pritchard is no mere curiosity hunter; he realizes that many of the Azande notions about witchcraft, and the ways in which the people use them, are not far removed from some of our own current ideas and practices about medicine and the chances of life; and he knows perfectly well that

though his book is entirely concerned with witches, witch-doctors, magicians and sorcerers, it covers only a very small part of Azande activity: "Most of their talk is common-sense talk, and their references to witchcraft, whilst frequent enough, bear no comparison in volume to their talk about other matters".

The Azande are a fairly numerous people living on the Nile-Congo divide. At present they form a homogeneous group, but they were formerly of many different tribes, with a variety of languages and institutions. As is natural, in such circumstances differences of social status play a great part in Zande culture. In particular, while the general rank and file are easily accessible, sociable, good-natured, assimilative, the royal class remain aloof, conservative, superior.

"Every Zande is an authority on witchcraft." If anything unusual happens, especially anything of an unfortunate character, it is attributed to some person—less often to some animal—in whom witchcraft resides as an inherent quality. This person does not need to do anything special in order to exert his influence; in fact, he cannot well help himself, for within him, whether he knows it or not, is some "witchcraft substance". Dr. Evans-Pritchard has himself never seen this substance, but it can be discovered by autopsy, and the evidence leads him to believe that it is the small intestine at a certain phase of digestive process.

Anyway, whatever it is, it is hereditary, and since it is a part of the body, it grows with the body, and becomes more potent as its possessor grows older. It can threaten misfortune, and then may be counteracted in various ways through the co-operation of oracles. It may produce death, and then must be avenged, though very little appears to be known about the precise operation of vengeance-magic.

In the early parts of his book, Dr. Evans-Pritchard describes, with copious illustration, what witchcraft is to the Azande, what sorts of things it can do, and what socially controlled processes there are for taking precautions against its more disastrous effects. It provides for these natives a kind of "natural philosophy by which the relations between men and unfortunate events are explained", and it gives them a "ready and stereotyped means of reacting to such events". So there is no kind of contradiction if a man treats a festering wound as due to witchcraft, and at the same time treats the wound as due to a spear or a splinter. Equally there is no contradiction if he should say that a death is caused by a weapon in some particular place, and at the same time by witchcraft in some other place. A good many Europeans have wished to verbalize all these actions or attitudes, and then to show that the different statements made together are mutually incompatible, and to prove from this that the native mind works in some manner peculiar to itself. But Dr. Evans-Pritchard puts the truth perfectly clearly: "We have to be careful to avoid in the absence of native dogma constructing a dogma which we would formulate were we to act as the Azande do. . . . The Zande actualizes his beliefs rather than intellectualizes them, and his tenets are expressed in socially controlled behaviour rather than in doctrines. . . . His ideas are imprisoned in action and cannot be cited to explain and justify action".

A person who is in a line of witches is probably inhabited by witchcraft; but he need not worry overmuch about that. Anybody can be a witch, and so he can live comfortably, respected, and even somewhat admired by his neighbours. A Zande who is worried about his health will go off to consult an oracle in the socially approved way. He may be a little downcast until he has taken the necessary steps to render the witchcraft quiet, but this is unlikely to carry him into downright illness. Also, contrary to the sort of opinion which has been expressed in some quarters, these people, at any rate, are no more likely to be thrown into a variety of mental disorders by their beliefs about ubiquitous witches than are most people in our own community when they read newspaper reports of road-accident statistics. The Zande, indeed, "is

never so happy as when he is consulting the poison oracle, and he easily banishes all other considerations from his mind when he is engaged upon this task of supreme interest". For him it is clearly as good as a visit to Harley Street is for many of us. Dr. Evans-Pritchard shows, moreover, the social value of many of the controlled methods for the consultation of oracles, as well as of the ways in which such practices may be abused. Destroyed for ever, in this case, at any rate, is the picture that when a people talk often about witchcraft and its potency for misfortune, they must be miserable, hag-ridden, harried and hunted by malevolent forces. They can be as curious, and, in their ways, as knowledgeable as anybody, about the sequences of natural events; and, when they come to the other questions about why certain sequences happen when they happen, they can get from their witch philosophy the same sort of satisfaction that others find in 'chance', or 'probability', or in different beliefs more dogmatically formulated.

In Part 2 of his book Dr. Evans-Pritchard considers witch-doctors; that is to say, the specialized profession among the Azande who have "vested interests in the knowledge of medicines" and are consulted when witchcraft is suspected. The witch-doctor is a diviner, exposing witches, and a magician, thwarting them. Here, if possible, the book becomes more interesting still. The topics discussed are: how the witch-doctor conducts his *séance*, what is the basis of Azande belief in the witch-doctor, how the novice is trained in the art, and the place of the witch-doctor in Zande society. The accounts of the technique of the doctor, of how he maintains his social prestige, of the ways in which he elicits just the sort of information which his vocation requires, of the skill with which he often meets individual desire and need and satisfies important social demands are both convincing and delightful to read. Anyone who has talked with witch-doctors in an African community, as I have done, and watched them at work, will be interested to find that Dr. Evans-Pritchard was "impressed with their ability" and that he thinks it probable "that as a rule men who show a strong desire to become witch-doctors have a higher degree of intellectual curiosity and greater social ambition than the ordinary Zande possesses". In view especially of the great amount of administrative trouble which has arisen in many parts of the British Empire owing to the adoption of purely repressive measures against the diviner and magician, it is particularly to be hoped that people responsible, directly or indirectly, for the government of native races will read and seriously consider this part of the book.

Dr. Evans-Pritchard next discusses various practices connected with oracles, their collection

and use, and deals finally with magic and sorcery, with some comments also upon native leechcraft. It appears that of late a number of associations have developed among the Azande for the practice of magic in assemblies. One of these is described in considerable detail, and it is demonstrated how a specific organization may be used to introduce new ideas and to spread them throughout the community, although the ideas themselves may have a much wider application than the avowed purpose of the organization would seem to imply.

Dr. Evans-Pritchard modestly hopes that his book will "be of service to political officers, doctors, and missionaries in Zandeland, and later to Azande themselves". If they will read it, it certainly will be of service to all of these; but it will also be of

wider value than this. Every social anthropologist should study it, not only for the wealth of information which it contains, but also as a model of well-controlled and sane methods of investigation. Everybody interested in the development of primitive science and the ways in which other minds than our own attempt to explain natural processes should read it, for it will correct a mass of popular and third-hand speculation concerning these matters. Further, everybody who is practically interested in native administration anywhere throughout the British Dominions ought to read it, for it will help him to understand the core of many difficult administrative problems and to solve them with a minimum of disastrous friction.

F. C. BARTLETT.

Chemical Stabilization

The Retardation of Chemical Reactions

By Prof. Kenneth O. Bailey. Pp. viii+479. (London: Edward Arnold and Co., 1937.) 26s. net.

THE problem of the supply of drinking water to troops sent to tropical stations was extremely difficult during the early part of the Great War. For removing the excess of chlorine used in sterilizing water, hydrated sodium sulphite was dispatched to places like Basra, Bagdad, etc., where the temperature goes up to 118° F. (48° C.) in the shade in summer. It frequently happened that by the time the sodium sulphite reached its destination, it was wholly converted by oxidation into sodium sulphate, which was useless as an 'antichlor'. Hence investigations were carried on to discover stabilizing agents or retarders of the oxidation by air of sodium sulphite. Hydroquinone (quinol) and other organic compounds when added even in traces were effective in preserving sodium sulphite from such oxidation.

Sodium sulphite, which is a valuable material in photography as well, and other useful substances like vitamins, butter, fats, cod liver oil, rubber, petrol, ether, chloroform, hydrogen peroxide, acrolein, and so on, are stabilized on a commercial scale against oxidation, polymerization, decomposition, etc., by the addition of chemicals, which in general can themselves combine with oxygen. The use of acrolein as a poison gas led the late Prof. Moureu and Prof. Dufraisse to study its stabilization by different reagents.

Not only is the subject of importance to chemists and industrialists, but physiologists also know that fats and especially carbohydrates act as protein

economizers in the animal body. Moreover, carbohydrates, pentosans, cellulosic materials, etc., when added to soil, cause nitrogen fixation and also preserve the soil nitrogen from too rapid oxidation and loss.

Prof. K. O. Bailey has collected the literature on the subject and has ably discussed it from the theoretical and practical points of view. After a brief account of the historical development, the author takes up the oxidation of phosphorus and the combination of hydrogen and oxygen. A number of retarders for both these reactions have been known for some time. He considers the mechanism of these oxidations from the point of view of the chain theory and goes on next to the oxidation of hydrocarbons and other compounds. This is followed by an excellent account of the work of Moureu and Dufraisse, who have given a great impetus to research in the retardation of oxidations. The slowing down of the oxidations of inorganic substances like sulphites, arsenites, antimonites, ferrous, stannous, cuprous salts and organic compounds like aldehydes, chloroform and other halogenated substances, adrenaline, carbohydrates and allied compounds, dyestuffs, etc., has also been discussed. It is interesting to note that the rancidity of butter, cod liver oil and similar substances is chiefly due to their partial oxidation by air, and many reducing agents such as hydroquinone and pyrogallol even in traces retard this oxidation and delay rancidity.

In recent years, 'anti-knock' compounds and their function in motor-car engines have been extensively studied, and Prof. Bailey has given an adequate account of this work with the various theories that have been put forward to account

for it. Existing theories appear to be inadequate, and further work is necessary.

The protection of rubber from deterioration, the preservation of hydrogen peroxide from decomposition and the prevention of metallic corrosion are also considered in this book. The function of retarders in the setting of plaster-of-Paris and cement is also discussed.

In the last portion, the decomposition of numerous organic and inorganic compounds, the reactions of halogens with hydrogen and other reducing agents and the retardation by water in the processes of esterification, saponification,

hydrolysis and the decomposition of organic substances by concentrated sulphuric acid, have been summarized. A brief account of the quenching of fluorescence and the after-glow of active nitrogen has also been included. There is a bibliography of 1,630 original papers at the end of the book.

The subject-matter of this book is of considerable practical and theoretical importance. Prof. Bailey's discussion of the diverse topics involved is clear and exhaustive, and presented in a very readable form. The book should be valued and widely read.

N. R. DHAR.

Reflections on Life

Life Here and Now :

Conclusions Derived from an Examination of the Sense of Duration. By Arthur Ponsonby (Lord Ponsonby of Shulbrede.) Pp. 289. (London : George Allen and Unwin, Ltd., 1936.) 10s. 6d. net.

THIS rather unusual book of reflections on life not only gives us in effect an interesting portrait of one of our greatest authorities on the type of data which characterize the 'commonplace book', but also an unexpected plea for individual action in support of high ideals, whether of peace or of social reform. Lord Ponsonby has long been occupied with thought on the nature of time and on our appreciation of its meaning and value in the art of living. He now advances a general argument based on an analysis of the sense of duration, and relying on the scientific attitude of Huxley's generation, he tilts valiantly at organized religion as he conceives it. The idea of personal immortality is challenged, and its rejection appears to be inspired largely by his contention that too much time is occupied in vain speculations about the future to the neglect of the present.

If Lord Ponsonby appears to overstress the logical part of man's nature, there is nothing in this finely written plea for more effective use of the immediate moment to control the duration of our living which can possibly impede that *rapprochement* between science and religion for which Smuts and others have been pleading. Not even those whose convictions he brushes on one side—not always on the most convincing grounds—can fail to recognize the dignity and sincerity of his plea for a better use of our present term, of the proper use of the new in the here, of the moment as it passes in our own environment. He gives us wise words on the small matters which make up the art of

living, but most will welcome the book for its inspiring idealism. Planning the future, he claims, is better for the mind than analysing the past, and if he is impatient with creeds it is perhaps mainly in so far as they impede progress.

Lord Ponsonby believes in individuality, and nowhere is this clearer than in his plea for a courageous stand for peace. "Our forefathers certainly would be unable to discover any element of glory in modern warfare; but they would observe in the world a noticeable depreciation of the value of human life." The warm human sympathies of the writer are as conspicuous as the sincerity of his thought and the lucidity of his diction, and they lead him to a final plea for action and service which is poles asunder from the frenzied plea of the demagogue to "do something". Its calm and dignified courage should win the sympathy of all who appreciate the inspiring personality imprinted upon that plea: "Now is the greatest of moments, the most real thing of which we can be aware. . . . To seize it as an opportunity means bracing ourselves up for action, decision, bite, endeavour . . . not vague resolutions but insistent occupation, not irresolute hopes but intent purposes, not languid aspirations but ready service, not 'Time will tell', but 'I will tell Time' . . . the errors of impetuosity are far less serious than the errors of caution and indolence and the enervating paralysis of procrastination. . . . There is no failure except in leaving off trying."

These are no pages from a dilettante's notebook, but a glimpse into the soul of one who has made time his servant, and himself compelled the hours to suit his intentions, the minutes to serve his purpose.

R. BRIGHTMAN.

Trade Marks in India

The Law of Trade and Merchandise Marks in India

By Dr. S. Venkateswaran. Pp. lxxx+767. (Madras : Madras Law Journal Office, Mylapore ; Calcutta : Law Book Co., 1937.) 20 rupees.

THE year in which an amending Trade Marks Bill is passing through Parliament in England is singularly appropriate for the appearance of a book on trade marks in India. The book is not only in itself an excellent and comprehensive guide to English trade mark law, but is also a most powerful argument for the trade mark legislation in India that its author desires. The position to-day in India is very much the same as it was in England before 1875 ; the owner of a trade mark can only attempt to protect his rights by a cumbrous passing-off action or by invoking the Indian Merchandise Marks Act, under which the onus is on him to prove his entitlement, and a successful action can give him neither damages nor an injunction.

Simplicity and a reasonable degree of certainty can only be attained by direct trade mark legislation, for which there has been a demand since 1877. Mr. Venkateswaran, the author of the work under notice, an examiner in the Indian Patent Office, has a melancholy tale to tell of the abortive efforts that have been made to secure such legislation. Agreement on the need has not been accompanied by agreement on the method, and India, unable to join the International Union for the Protection of Industrial Property, by reason of the absence of trade mark legislation, has only privately run registers to show as the result of sixty years of persuasion, petition and argument by chambers of commerce and other interested bodies in India and the United Kingdom.

One of the great difficulties about trade marks is to be found in the fact that they are dealt with in most countries by the same Government department that handles patents. This encourages the idea that the two forms of protection are closely parallel. In fact, patents and trade marks have considerable fundamental differences, which were not clearly realized, for example, in the United States, for the greater part of the nineteenth century. The delay in getting adequate legislation in India will be regarded less harshly when it is realized that, in the United States, Thomas Jefferson was recommending trade mark legislation so early as 1791, and not until 1905 was there water-tight legislation there, a first Act of 1870

having been declared, *more Americano*, unconstitutional.

Mr. Venkateswaran, who is completely up to date, has a good deal to say about the Goschen Committee on Trade Marks, the report of which, issued in 1934, forms the basis for the English Trade Marks Bill. He is not only in favour of Indian trade mark law following the British model in general but also advises, with a varying degree of insistence, the adoption of most of the recommendations of the Committee. He approves, for example, of assignment in gross, but is doubtful of the applicability of Clause 8 to India, feeling that, in her present state of industrialization, abuse might arise there if the names of "registered users" as well as those of the actual proprietors could be entered on the register. Nor is he altogether happy about the marks, introduced in England in 1905 and used to indicate certification by some competent authority of the origin, material, accuracy, etc., of goods so certified. On one point, the division of the Trade Mark register into Part A and Part B, he advises a clean breakaway from English practice. He feels that the effective demand for Part B is relatively small in Great Britain, and in India can be ignored. But he goes further and states that the difference between the requirements for the two parts is neither clear nor well-explained by the English courts, and refers in support to Mr. Justice Romer's remarks in the "Liverpool Cables" case to the effect that it was doubtful whether there was any difference between "adapted to distinguish" and "capable of distinguishing", and that if a mark did in fact distinguish, it should be adapted to distinguish.

Cotton marks, for very obvious reasons, are of the first importance to India, and Mr. Venkateswaran has very definite views about the shape that relevant Indian legislation should take. He would allow the registration of word marks for cotton goods but not that of line headings. He quotes with approval in connexion with word marks some of the rules of the Bombay Mill Owners' Association, which has a register of trade names, but suggests that the exclusion of the names of gods, goddesses and mythological persons from this private register is definitely on the harsh side and sets an example not to be followed when an official register is set up.

There should be no disagreement about the need for trade marks legislation in India, and there should be the minimum of discussion before it is decided that the legislation must be on a purely

Federal and not on a States basis, the experience of the United States alone being quite sufficient to make a decision in favour of a strictly central system inevitable. Sufficient has been said, however, to show that there will be considerable debate on detail and even on certain major points of principle before trade mark India leaves the 'law-less' company of Monaco, Sarawak and the Solomon Islands and is able to take her place as a full member of the International Union.

When active consideration of prospective legislation for India does take place, it is inconceivable that Mr. Venkateswaran should not be called into consultation, for his book shows him to have both a masterly grasp of principle and a keen perception of detail. Sir Courtney Terrell, chief Justice of the Patna High Court, says in an introduction to the book that it astonished him to find "that legal

principles should be so admirably expounded by one who is not a professional lawyer" and reinforces from his wide experience at home and in India the author's demand for action to end the chaos that exists in a country where no action for infringement of a trade mark can lie and the actual form of action possible—and the decision—may vary from one provincial court to another.

In a work which was merely an industrious compilation, the fact that there were some two thousand five hundred actions listed in the table of cases would normally go to show the practitioner that the book was worth acquiring. It is mentioned here only to indicate that though Mr. Venkateswaran has produced a powerful large-scale propaganda document, he has at the same time written a first-class text-book very suitable for the Indian and far from being unsuitable for the English student.

A Survey of Psychopathology

Modern Discoveries in Medical Psychology
By Dr. Clifford Allen. Pp. x+280. (London: Macmillan and Co., Ltd., 1937.) 8s. 6d. net.

DR. CLIFFORD ALLEN gives a general survey of the recent history of psychopathology suited for the medical man or the intelligent layman. He rehabilitates Mesmer as an honest worker whose results, though given a wrong explanation, were nevertheless worthy of that investigation which was denied them. He might have shown the parallel between Mesmer and Charcot, for the latter's results were genuine but misunderstood phenomena, the anatomical nervous system taking the place of Mesmer's magnetism in a spurious explanation.

Janet's work, with his theory of dissociation of consciousness, prepared the path for Freud, and to this period belong Morton Prince's studies of multiple personality. The description of the gradual nature of Freud's discoveries helps to their understanding, though the necessary condensation of material does rather less than justice to this important stage of development. Dr. Allen defends the use of what he perhaps wrongly calls mechanistic devices and mental mechanisms, by which he means those theoretical constructions giving a spatial and dynamic view of mental processes. One might, however, object to the personification by which the superego "can still wreak its revenge on the patient by making him have a terrible sense of guilt, and sometimes compel him to do something for self-punishment".

The author is fair towards Adler's theories, but, like everyone with practical experience of analytical procedure, finds them incomplete and unsatisfying, though clinically useful because of their easier demands and avoidance of emphasis upon sexuality. Jung receives credit for his work on psychological types, but the author accuses him of spoiling the technique of Freud "by the addition of a hotch-potch of religion and mythology which cannot act in any other manner than as suggestion".

Kretschmer and Pavlov are adequately handled, but only one phrase (on p. 277) indicates that Pavlov is by some people placed in opposition to Freud, and regarded, indeed, as having made psychology unnecessary. This opposition can be understood only by a knowledge of the historical conflicts in medicine between animists and vitalists on one side and iatro-physicists on the other, which form a continuous series with present controversies and depend not upon knowledge but upon basic differences of outlook. This is a field of interest that Dr. Clifford Allen has not approached.

The author's aim of presenting current views is efficiently carried out, but a unifying summary of the position to-day would have been welcome. There is fortunately among the younger generation of psychiatrists and psychotherapists an agreement upon certain fundamental principles which the author's scheme of presentation cannot convey to the reader. His literary style is straightforward and simple, and he has made the subject intelligible without shirking its difficulties.

M. C.

A Text Book of Trigonometry :

for Colleges and Engineering Schools. By William H. H. Cowles and James E. Thompson. Pp. x+373. (London : Chapman and Hall, Ltd., 1936.) 12s. 6d. net.

So many books on trigonometry are published that, when a new one makes its appearance, especial characteristics are naturally looked for. The present volume is much larger than usual, but it surveys a wider field as the course is intended to be a preparation for the study of higher mathematics, physical science and engineering. The authors state that several new and unique features are developed in the presentation of the subject, and this claim is well substantiated, for the fundamental principles of trigonometry are not dealt with in a piecemeal fashion so common in many books. Circular functions are, for example, defined generally at the beginning; radian measure, too, is introduced at once and used throughout the course. The discussion of complex numbers, expansions in series and general analytical trigonometry is not only thoroughly sound, but also is more interesting and complete than is usual. Two chapters are devoted to the manifold applications of the subject to surveying, mechanics, geodesy and astronomy. Instructive chapters are also given on logarithmic computation and the use of the slide rule, whilst emphasis is rightly laid upon accuracy, precision and significant figures in all numerical work. Considerable attention is also directed to the analysis of problems and the reduction of the formulae deduced to a suitable form for numerical evaluation.

The student is provided with a large number of varied exercises to which answers are supplied, and some very useful tables are given at the end. The book is certainly well adapted to the purpose for which it was written, and reveals that trigonometry is something far more interesting than the mere solution of plane triangles.

F. G. W. B.

Moeurs et coutumes des indiens sauvages de l'Amérique du sud

Par Marquis de Wavrin. (Bibliothèque scientifique.) Pp. 656+16 plates. (Paris : Payot et Cie, 1937.) 60 francs.

In this impressive work of more than six hundred closely printed pages, the Marquis de Wavrin has embodied the results of fifteen years of travel and observation on five journeys of exploration among the less-known Indians of South America. He has covered a wide territory, for there is scarcely a part of the continent which he has not visited in that period; but his most entertaining and informative (in the anthropological sense) material is drawn from the various peoples of the Amazonian region. His method is anecdotal rather than systematic, except that he has classified his data into chapters according to subject, covering material culture, social organisation, relations of the sexes, religious beliefs and folklore.

Although amusing and instructive enough to read, the unfortunate lack of method, by which the data

from widely separated tribes are massed together without order or discrimination, makes it a source book for the delver after facts, rather than an ethnographical treatise. This is especially to be regretted as the author is an acute and careful observer. Perhaps he will conform to the suggestion made by M. de Créqui-Montfort in the preface, and produce a more formal account of his results later.

Thermodynamic Theory of Affinity :

a Book of Principles. By Prof. Th. De Donder and Prof. Pierre Van Rysselberghe. Pp. xx+142. (Stanford University, Calif. ; Stanford University Press; London : Oxford University Press, 1936.) 13s. 6d. net.

THEORIES of affinity have interested physical chemists for a considerable time; moreover, greater recognition is now being given to such concepts as aids in the interpretation of experimental results.

The book now before us represents an essentially synthetic outlook, and the introduction of the terms "uncompensated heat" and "degree of advancement of a reaction" gives the basis upon which it is written. The former expression is simply the dQ' of Clausius under a slightly new guise, the latter (ξ), however, is decidedly interesting as representing the state of a chemical system; its time-derivative is a rate, which leads at once to a criterion of equilibrium. These two quantities are combined in the fundamental hypothesis that $dQ'/d\xi$ is independent of any particular relation between the pressure, temperature and "degree of advancement" during a reaction. A detailed analysis leads the authors to identify this coefficient with the affinity.

In general, the treatment developed in these pages is suitable for obtaining straightforward solutions to problems like Le Chatelier's principle; another volume is promised, to deal with applications and numerical examples.

F. I. G. R.

Freud and Marx :

a Dialectical Study. By R. Osborn. Pp. 285. (London : Victor Gollancz, Ltd., 1937.) 8s. 6d. net.

IN this comparative study—the first of its kind to be undertaken—the author emphasizes the importance of a closer study of psycho-analysis by Marxists, of Marxism by psycho-analysts and of both by the general public. He maintains that as psycho-analysis teaches us to recognize that unconscious motives are at work in us all, the curriculum of the Marxist should include a study of the unconscious mind, both Freud and Marx being pioneers in revolutionary psychological discoveries.

The work contains a study of the relationship between Freudian and Marxist theories regarding primitive society, the materialistic conception of history, religion and dialectical materialism. In conclusion, the author declares that "the Marxist without knowing something of the subjective side of man's life will remain one-sided, as will the Freudian who misconceives the objective situation in which man's subjective life expresses itself".

Physical Investigations on Falling Snow*

[In this article I have used the nomenclature with which I have endeavoured to standardize the English names of the various snow forms. Prof. U. Nakaya, who had not seen my work when preparing his papers, has now agreed to follow this, except that he proposes to continue to call a particle of falling snow a "snow crystal" in preference to my "snowflake". As all snow, whether falling or having lain on the ground for months, is crystalline, the word "snow crystal" is likely to lead to ambiguity. I admit that "snowflake" ("simple" for a single crystal; "compound" for an assemblage) is not perfect, but until a better word is devised it must, I fear, remain.—G. S.]

THE researches which form the subject of this article were carried out by Nakaya and his assistants at Sapporo and Mt. Tokai in the island of Hokkaido, the most northerly member of the Japanese archipelago. Ukitirô Nakaya, who is professor of physics at the Hokkaido Imperial University, has been studying the general subject for many years, but the special work of which the results are now given was done during the winters of 1933–35.

Nakaya commences his researches with a preliminary examination of the problem of snowflake structure in an attempt to find a method of classification for the many varying types, and of ascribing to each the conditions favouring its development. He wonders at the marvellously symmetrical form of the dendritic branches of a flake. "There is apparently no reason for a twig . . . to grow from one main branch when a corresponding twig happens to extend from another main branch. . . . We must suppose the existence of some means which informs other branches of the occurrence of a twig on a point of one branch." He suggests, but with doubt, the possibility of a bud of the twig causing a distortion of the lattice, which is transmitted to the other branches.

It seems simpler, however, to believe that, as I have suggested elsewhere, "changes in the scheme of ornamentation are caused by the flake passing

through different temperature and concentration gradients", and clearly each portion of the flake would normally come under these changes at the same instant and so symmetrical growth would be promoted.

(a) FROST CRYSTALS (photograph by Mr. Hatakeyama).

(b) CORRESPONDING SNOWFLAKES (photograph by U. Nakaya). MAGNIFICATION, 21.

Fig. 1.

One of the most important features of Nakaya's work was the designing of an apparatus for making hoar and rime under controlled conditions of temperature and humidity. Both these forms, incidentally, are crystalline, and I must respectfully join issue with Prof. Nakaya in his statement that rime, which consists of frozen water droplets, is amorphous. Previous to this he had shown that

* Based on a series of eight papers by Prof. U. Nakaya and his assistants, published in the *Journal of the Faculty of Science, Hokkaido Imperial University*, under the following titles:

(1) "Snow Crystals observed in 1933 at Sapporo and some Relations with Meteorological Conditions" (II, 1, No. 5, Feb. 1934).

(2) "Classification and Explanation of Snow Crystals observed in the Winter of 1933–34 at Mt. Tokai and at Sapporo" (II, 1, No. 6, Dec. 1934).

(3) "On the Electrical Nature of Snow Particles" (II, 1, No. 6, Dec. 1934).

(4) "Simultaneous Observations of the Mass, Falling Velocity and Form of Individual Snow Crystals" (II, 1, No. 7, Oct. 1935).

(5) "On the Correspondence of Snow and Rime Crystals" (II, 1, No. 7, Oct. 1935).

(6) "On the Artificial Production of Frost Crystals, with reference to the Mechanism of Formation of Snow Crystals" (II, 1, No. 7, Oct. 1935).

(7) "Notes on Irregular Snow Crystals and Snow Pellets" (II, 1, No. 8, April 1936).

(8) "General Classification of Snow Crystals and their Frequency of Occurrence" (II, 1, No. 9, Dec. 1936).

hoar crystals (which result from the sublimation of water vapour upon fixed objects as opposed to the moving nuclei of snowflakes) correspond in form with the flakes. In other words, we get needle, plate and dendritic forms of hoar just as we do of the snowflake (see Fig. 1). Arguing by analogy, he assumes the following facts for snow: that at the highest supersaturation the needle type develops, next the dendritic, then an 'intermediate' form, then the plate, the pyramidal, the prism, in that order, and, at the lowest supersaturation, prisms with one side extended in a plane. Nakaya notes that this rare type of snowflake, although occasionally seen at Sapporo, has apparently never been recorded elsewhere.

The most surprising result is that the needle and prism appear to occupy different ends of the scale, indicating not merely different conditions of formation but perhaps even a basic difference in type. This is, I think, quite contrary to general belief, and further proof will no doubt be forthcoming. Two different types of needle are described—a single elongated form, and a bundle of thin pillars. The latter, Nakaya believes, indicates the advent of warmer conditions.

Full justice cannot be done to this line of research in the confines of a brief account, but its results, if substantiated, ought to prove of great meteorological value. Nakaya realizes this in the following words: "The delicate form and design of a snow crystal must form by developing step by step while it is falling through the various strata of the atmosphere, and the authors consider that the structure of the atmospheric layers may be inferred to some extent by investigating in parallel the structure of snowflakes." With this I cordially agree; before having the advantage of seeing Nakaya's work, I had written, "An elaboration [of the conditions under which snowflakes grow] might prove of the greatest value to meteorology", although, as Nakaya says elsewhere, no simple relationship has yet been found; nor do I think that the problem can be solved until captive balloon ascents for the investigation of the upper air can be systematically made.

Nakaya's views on the subject of irregular or malformed snowflakes are most stimulating. Although stressing the exquisite symmetry of ordinary snowflakes, he points out that absolute and complete symmetry is never in fact attained, and that complete malformations are far more common than previous writers, Bentley for example, have led us to believe. Nakaya describes, *inter alia*, flakes deformed by the subsequent attachment of a second nucleus on which further growth takes place. Other deformations are, he says, due to the supply of water vapour from a 'one-sided direction', due, I imagine, to the flake

falling irregularly. These irregular crystals are observed to fall in great frequency for a few minutes and then cease entirely. From this Nakaya has been led to think that these irregularities are not merely chance occurrences, but are caused by definite and, ultimately perhaps, ascertainable causes. I suggest that another factor may be responsible for the malformation of snowflakes. Dewar showed that electrical stimuli have a strong accelerating influence on the sublimation of water vapour. Is it not possible that these in some way, as, for example, by the sudden advent of a new electrical charge, might cause irregular growth?

Nakaya also states that "a snowfall usually consisted of several types of snow and sometimes almost all types of flake were found in a single snowfall. Occasionally only dendritic plane flakes were observed at a given moment. These would continue for a short time, and then another type would begin to mix with them; after some time, a third type would take its place; and so on". A graphic table shows these happenings in detail. The investigator everywhere emphasizes that his results are those found in Hokkaido only. I have, however, on many occasions observed this sequence of types in the Alps.

Nakaya commences the paper which deals with the classification of snowflakes, and which gives the impression of being the *raison d'être* of these researches, with notes on previous classifications such as those of Nordenskiöld, Hellmann and Pernter, which divided the flakes into plates, columns and their combinations. Humphreys added triangular plates and twelve-sided plates. "These classifications," Nakaya writes, "are inclined to attach too much importance to the regular crystals or the simpler form. The feature of the present classification is that we regard all the flake types as of equal importance, such as irregular [plane] crystals and those consisting of a spatial assemblage of plane branches, both of which are, as a matter of fact, no less frequently observed among the natural snow crystals." This last point, which I have italicized, is stressed throughout Nakaya's work.

THE GENERAL CLASSIFICATION OF SNOW CRYSTALS

(In this case Nakaya's nomenclature has remained unaltered. *Grasspel* is, of course, our soft ball.)

- I. Needle crystal.
 - (1) Simple needle.
 - (2) Combination of needles.
- II. Columnar crystal.
 - (1) Simple column.
 - (a) Pyramid.
 - (b) Bullet type.
 - (c) Hexagonal column.
 - (2) Combination of columns.
 - (a) Combination of bullet crystals.
 - (b) Assemblage of short columns.

III. Plane crystal.

- (1) Regular crystals developed in one plane.
 - (a) Stellar form.
 - (b) Plane dendritic form.
 - (c) Crystal of areal extensions.
 - (d) Plate.
 - (e) Plate with extensions at corners.
 - (f) Stellar crystal with plates at the ends of branches.
- (2) Crystal developed from two nuclei.
- (3) Malformed crystal.
- (4) Spatial assemblage of plane branches, with a stellar base.
- (5) Spatial assemblage of plane branches, radiating type.

IV. Combination of column and plane crystals.

- (1) Column with plane crystals.
- (2) Twelve-sided crystal.
- (3) Combination of bullets with plane crystals.

V. Columnar crystal with extended side planes.

VI. Crystal with cloud particles and Graspel.

- (1) Crystal with droplets.
- (2) Thick plate.
- (3) Graspel-like snow.
- (4) Graspel.

VII. Amorphous snow particle

What Nakaya terms a "bullet" is very much like the cup crystals so often found in hoar deposits, but never hitherto recorded in falling snow*. I also suggest that the "amorphous snow" consists, in reality, of wind-comminuted snow particles. Nakaya is able to confirm the belief that columnar crystals fall when the upper air temperature is low, but states, as I have always maintained, that temperatures at the surface have little or no bearing on this.

This classification—or perhaps it should be called grouping—will probably in time give place to one based on more essential crystallographic factors, and even, perhaps, on varying internal structures of the ice, but it certainly goes further,

Fig. 2.

PLANE DENDRITIC SNOWFLAKE. MAGNIFICATION, 27.5.

and gives us a far better idea of the problem, than any that have preceded it.

Among what might be called the by-products of the researches the following point is of special interest, namely, that the mean thickness of a large number of dendritic flakes measured is

0.011 ± 0.0015 mm. and is remarkably constant, the smallest being 0.009 mm. and the largest 0.015, although the diameters of the flakes measured varied from 2.35 mm. to 5.0 mm.

On the subject of the formation of soft hail, Nakaya found that it has a very low density, and

Fig. 3.

HEXAGONAL PLATE WITH DENDRITIC EXTENSIONS. MAGNIFICATION, 36.2.

therefore possesses large interstitial air spaces. He repeats the fairly well-known fact that all degrees of development of soft hail can be found, from snowflakes decked with a few frozen cloud-droplets to assemblages of ice pearls entirely hiding the flake. The satisfactory theory of the development of conical soft hail units put forth by Prof. Köhler* had probably not been seen by Prof. Nakaya.

Some space is devoted to the sizes of snowflakes. I believe, however, that conditions often favour continued growth during travel over a very long continued distance, so that size is largely dependent on length of travel and is thus fortuitous. Nevertheless, the notes on the relative sizes of the various types are interesting.

Dealing with the electrical nature of snow, Nakaya found that "the number of the negative particles in general far exceeded that of the positive, being 63% of the total 1474 particles observed". When (frozen) water droplets were attached to the particles, the charge was predominantly positive.

Referring to the subject of the fall of individual flakes in relation to their mass and shape, a series of averages is tabulated as follows:

	Diameter (mm.)	Mass (mgm.)	Velocity (cm/sec.)	Ratio of velocity to that of corresponding rain-drop*
Needle	1.53	0.004	50	1/2
Plane dendritic	3.25	0.043	31	1/6
Spatial dendritic	4.15	0.145	57	1/5
Sundry small flakes	3.15	0.054	50	1/4
Flake with droplets	2.45	0.176	100	1/5
Soft hail	2.13	0.80	180	1/2.5

Each of the eight papers is illustrated with carefully captioned photomicrographs, from which those in this article have been reproduced. Nakaya's technique of photographing snowflakes is exquisite and far superior to any that I have seen. While following the general method employed by W. A. Bentley, he gains both in accuracy and, incidentally, in artistic effect by not trimming the margins of the flakes, and by reproducing the photographs on a light instead of a dark background. Remarkable and beautiful as was Bentley's work¹, its re-publication has lost in scientific value by the omission of the degree of magnification and of meteorological conditions obtaining at the time of the collection of the flakes. Nakaya's work is a continuation of and improvement on Bentley's.

What we must now hope is that Prof. Nakaya

will continue his researches. Some of his results are only tentative, and some of his later work admittedly negatives his earlier, so that a summarized version of the results of the whole eight papers in the light of his most recent experiments would add greatly to their value. Be all that as it may, there is no doubt that the work in total adds very considerably to our knowledge of the nature of falling snow.

Mendel, Morgan and Genetics

By Prof. E. W. MacBride, F.R.S.

THE modern science of genetics has acquired an enormous extension. As Prof. McDougall has said, it has swept over North America like a whirlwind. Everywhere chairs in genetics have been established, nay more, in some places special chairs in 'Drosophily' devoted to the exclusive study of this type-animal. Its votaries claim that in this science are to be found the solution not only of all the questions of the origin, propagation and improvement of our domesticated animals and cultivated plants, but also of the origin of species and evolution. Nevertheless, as time went on, the fair prospects of the science darkened. The hope of getting an unlimited number of new and valuable varieties was disappointed. As one of the professors of this science has ruefully expressed it, "The qualities that mendelize are not those which are of any value to farmers and those which farmers value do not mendelize." Anyone who reads, as I do, the minutes of the Agricultural Research Council, which contain an account of all the agricultural experiments seeking Government aid which are being carried out in Great Britain, must be struck with the fact that Mendelism is scarcely ever mentioned.

If 'genetics' be defined as the study of heredity free from presuppositions, then this study will be readily acknowledged to be a most important branch of the science of biology. But in practice, 'genetics' means the interpretation of hereditary phenomena according to fixed rules or postulates which were worked out by the late Dr. W. Bateson in Great Britain and by Prof. T. H. Morgan in the United States.

The discovery by Mendel of the facts of alternative inheritance and their rediscovery by Bateson and Correns were hailed as the greatest advance in biology since the publication of "The Origin of Species". The first question to be asked is whether what Bateson called 'unit-factors' and which are more frequently termed 'genes' have really the significance which has been attached to them. Mendel himself did not suppose that the phenomena of alternative inheritance covered more than a small part of heredity, but the persistent effort of all subsequent geneticists has been to crush all cases of heredity into this mould.

Bateson, who had the advantage of a broad education in biology at a time when in fame and brilliance the Cambridge School was at its zenith, really did most, especially in his later years, to clarify the position. He showed that alternative characters or 'allelomorphs', as he termed them, were related to each other in such a way that the dominant was characterized by something which was absent in the recessive. This definition was afterwards altered to stronger and weaker expressions of the same character. The classical experiments on peas will illustrate this point clearly. Yellow peas are dominant to green peas. But all peas when immature are green; the yellow pea on ripening transforms its chlorophyll into etiolin whereas the green pea stops short in its development. Similarly, round peas are dominant over wrinkled peas. Again, all young peas are round: in dominants, the round form is retained

owing to the transformation of an adequate amount of sugar into starch, but in the wrinkled peas less starch is found and an amount of sugary solution remains, and when this dries up in ripening, a shrinkage occurs which leads to a wrinkled seed-coat. When, therefore, two parents mate and each has some of the specific characters in their dominant form, this merely means that some of the specific characters are more strongly marked in the mother and some in the father. It is sometimes possible to mate two forms such as a regular sea-urchin and a heart-urchin which have been distinct for millions of years, and in the offspring the paternal influence may sometimes show and at other times the maternal. In picking out a recessive as a new variety to be propagated, we are really selecting a weakened form. As he grew older, Bateson became more and more convinced that an increasing number of cases of inheritance could not be brought under the Mendelian laws at all.

But the great extension which 'genetics' has attained in recent years is undoubtedly due to Morgan. He has, with a certain amount of justice, been termed the founder of the science of genetics. As is well known, in the ripening of the nuclei of the sexual cells a stage occurs which is known as 'meiosis'. In this stage, the paternal and maternal chromosomes approach each other in pairs and appear to come into actual contact with one another; they then separate, and half go to one pole of the nucleus and half to another. The nucleus then divides and the number of chromosomes is thus reduced to one half: the sexual cell is now ready to unite with another one with a similarly reduced number of chromosomes and so in the zygote the full number is restored. Now, according to Morgan, when meiosis takes place, the pairing chromosomes are very long and spirally twisted, and Morgan assumes that they break and exchange portions of their substance. If, then, the Mendelizing factors are based on discrete material particles situated in definite positions in the chromosome, the transference of dominant characters from one partner to another could be accounted for. Further, if two factors were situated near each other in the chromosome, it might be expected that the break would occur in such a manner that the separated piece would contain both factors. In this way, the association of two factors in inheritance was explained. The farther apart the position of the factors in the chromosome the more seldom would they be included in the same broken-off piece, and by the relative frequency of their association enthusiasts have attempted to construct a map of the chromosome and even to reckon the distance of two factors (in 'centimorgans') from each other.

It may appear to some readers that this whole theory is a rather risky castle of cards to erect on the basis of certain very dubious assumptions; and it is one of the main purposes of this article to show that these assumptions are incorrect, and consequently the whole chromosome theory falls to the ground. The question which we wish to put is whether the appearances of two long chromosomes slightly curved around one another are really an expression of meiosis or not. In my opinion, this question has been definitely decided in the negative by two researches, namely, "The Spermatogenesis of *Lepidosiren paradoxa*" (*Quart. J. Micro. Sci.*, 57, 1911) by Dr. W. E. Agar of Glasgow (now professor of zoology in the University of Melbourne) and "The Meiotic Phase in Vertebrates" by Prof. C. E. Walker of the Department of Cytology in the University of Liverpool. The latter research was published in two papers, namely,

Fig. 1.
THE 'FIRST' MEIOSIS
OF *LEPIDOSIREN*

Fig. 2.
THE 'SECOND' MEIOSIS
OF *LEPIDOSIREN*

"The Meiotic Phase in *Triton vulgaris*" (*Proc. Roy. Soc.*, B, 98; 1925) and "The Meiotic Phase in Certain Mammals" (*Proc. Roy. Soc.* B, 99; 1926).

Agar's researches were suggested to him by his teacher, Prof. Graham Kerr. This was a stroke of genius on Prof. Kerr's part. He argued thus: if so much importance is attached to minute details in the ripening process of the nucleus, would it not be essential to study them in the largest nuclei available? He knew well that the nuclei of the sexual cells of the testes in *Lepidosiren* were gigantic, so large indeed that it is impossible to include one of them as a single microtome section.

Agar found the ripening process beginning with the apparent apposition of two long chromosomes in the manner described by Morgan, and as he was at the time an orthodox geneticist, he interpreted it in the same manner. But to his amazement, when the putative meiotic partners separated, they shortened and condensed and the same partners then underwent a *second meiosis* during the ripening of the same nucleus! The so-called first meiosis as described by Agar is shown in

Fig. 1; the second in Fig. 2. In the 'second' meiosis it can be seen that the chromosomes are reduced to short rounded nodules, and any supposition that they could break and exchange pieces of substance is obviously ludicrous.

But Agar's supposition that the same two partners could undergo meiotic pairing twice in the same ripening cycle is clearly incredible, and the account given by Dr. Walker unravels the mystery. By his researches, which were begun on the newt in his first paper and continued on several mammals in his second paper, he has proved conclusively that Agar's 'first meiosis' is not a meiosis at all but a belated ordinary division of the nucleus. This begins in the telophase of the preceding division of the sexual cell. When this division is complete and the daughter nuclei are passing into the resting phase, the telophase 'filaments' can be seen to be split. In the resting phase this split disappears. But in the subsequent stage of activity, when long thin threads begin to be differentiated (the so-called leptotene stage), the split reappears and the separating chromosomes have been mistaken for meiotic partners. The pictures drawn by enthusiastic geneticists of long chromosomes with nodular thickenings opposite each other as proofs that similar 'genes' attract one another, are simply the expression of the division of moniliform chromosomes.

If, then, it is impossible to talk of 'genes' being in any particular chromosome—or of breaking and crossing over—it is difficult to see what remains of modern 'genetics'. As readers of NATURE are well aware, I am convinced that functional heredity, in other words, the handing on in some degree of habits acquired in one generation to the next, has been finally proved to be true, and this principle once admitted is sufficient to explain evolution and the origin of natural races and species. But the question of the origin, nature and inheritance of mutations, otherwise 'sports', remains to be dealt with. On this subject a great deal of light has been thrown by Prof. Mohr, of the University of Oslo, in a paper entitled "Über Letalfaktoren mit Berücksichtigung ihres Verhaltens bei Haustieren und beim Menschen" (*Zeitschrift für induktive Abstammungs- und Vererbungslehre*, 41; 1926). He shows that in *Drosophila* and in other forms an astounding number of mutations are what he terms 'lethal' or 'sub-lethal'. In *Drosophila*, the so-called 'modifying' factors which by themselves produce no outward visible effect and indeed whose existence is assumed in order to force the facts into the Morgan scheme, produce no effect on the viability of the insect. These he places in fanciful comparison at the red end of the spectrum. As we pass towards the yellow and green we encounter

mutations which make a marked difference in the appearance of the insect, and these decrease the viability until in the blue we encounter the sub-lethal mutations which injure their carriers so much that they can only be reared in a cross with a normal form. We finally reach the lethal factors in the violet, which even in a cross cause the death of their carriers. He shows further that such mutations are distributed over all the chromosomes and that new lethal factors are continually coming into being.

The obvious conclusion is that all mutations are of the physiological nature of damage to the growing powers of the germ, and when we consider the known artificial means of producing mutations, such as X-rays, heat, etc., applied to the eggs, this conclusion is so clear as scarcely to require statement. These agents kill the majority of eggs subjected to their influence: some resist them unaltered and some are half-killed and grow up to produce the mutations. Beneficent mutations which could survive in the struggle for existence are figments of the imagination.

Johannsen's demonstration that in a 'pure line' fluctuating variations are non-heritable marks one of the great advances in evolutionary knowledge, for it destroyed the basal assumption of the classical Darwinian theory that heritable variations in all directions are constantly occurring, some of which may *chance* to fit the environment and so be preserved. It was he who invented the term 'gene' as the cause of a mutation. About this word he says ("Some Remarks about Heredity," *Hereditas*, 4, 1923): "I introduced the word 'gene' when I was possessed by the antiquated spirit shown in Galton's, Weismann's and Mendel's viewpoints. Here we shall try to exterminate in genetics the term 'unit-character' because it indicates a notion inadequate and noxious for genetics. The most important part of the genotype does not seem able to segregate into units; as yet we are operating with characters which are superficial in comparison with the fundamental specific organic nature of the organism. However we try to analyse a genotype into factors we must remember that the characters of the organism, that is, its phenotypical features, are the reaction of the genotype *in toto*. Mendelian units *per se* are powerless. Are the experimentally demonstrated units anything more than expressions for local deviations from the original normal state of the chromosomes? *The Weismannian distinction between germ-plasm and soma, that is, absolute independence, does not exist in reality.* 'Gene' has nothing to do with De Vries's expression 'Pan-genes' and their behaviour as units; the phenotype is the reaction of the genotype (nature) with the ambient conditions (nurture)."

Obituary Notice

Prof. Hans Reck

PROF. HANS RECK, professor in the Institute of Geology and Palaeontology of the Friedrich-Wilhelm University, Berlin, died suddenly of heart-failure at Lourenço Marquez on August 4, at the age of fifty-one years. He was on his way from Natal to Lake Eyaasi, Tanganyika Territory, to examine the locality where Dr. Kohl-Larsen discovered a human skull in 1935 (NATURE, 138, 1082; 1936).

Hans Reck was born in Würzburg on January 24, 1886. He studied geology at the Universities of Berlin, of Munich, where he graduated as Ph.D. in 1910, and of London, at University College. During his undergraduate years he visited Iceland in company with his future wife, Fräulein Ina von Grumbkow, who survives him. In 1912 he was appointed leader of the Tendaguru Expedition of the University of Berlin; in 1913, leader of the Geological Expedition to Central Africa sponsored by the Royal Prussian Academy; at the end of 1913, leader of the Olduvai Expedition of the Universities of Berlin and Munich; and during the years 1915-19 he held the post of Government geologist in German East Africa.

After the Great War, Reck had not the same opportunities for work in the foreign field. Nevertheless, he twice visited Santorin, in 1925 and 1929. He was a member of the second Olduvai Expedition, in 1931, under the leadership of Dr. L. S. B. Leakey, and in 1932 visited South Africa to collect fossil reptiles. He left Germany at the end of September 1936 to carry out researches in the Cameroons, South Africa, Tanganyika and Kenya Colony; this trip was interrupted by his untimely death.

Reck's work on the geology of East Africa is

inadequately represented by a number of scattered papers. As editor and part author of the "Wissenschaftliche Ergebnisse der Oldoway-Expedition, 1913", he had the satisfaction of seeing the palaeontological results published in full; but the difficulty of raising funds caused many delays, and his account of the geology, which was to appear at a later date, was left unfinished. Nor did he issue any technical description of the giant caldron volcanoes, every one of which he had climbed. Nevertheless, he was a great pioneer in this field, and his influence on post-War research cannot easily be estimated.

Most of Reck's published work relates to volcanoes, on which he was a leading authority. He appears as a *Mitautor* in the first part of the *Zeitschrift für Vulkanologie* (1911), and as joint editor in 1923. In addition to many papers and numerous reviews contributed to the *Zeitschrift*, he published in 1923 "Die Hegan Vulkane" and "Physiographische Studien über vulkanischen Bomben". An exhaustive monograph on Santorin, completed just before he began his last journey, is in the press.

Tall, fair, and blue-eyed, Reck was a Bavarian of the finest type. His sunny disposition and upright character endeared him to all who had the privilege of his friendship. Himself incapable of an ungenerous thought or act, he was unable to understand them in others. In addition to his scientific pursuits, he found time to form a small but choice collection of Arab art, to become a gifted pianist, and to cultivate the delightful literary style which appears in "Oldoway, die Schlucht des Urmenschen", and in "Buschtaufel", a volume of light-hearted stories of the campaign in East Africa and of life as a prisoner of war in Egypt.

A. TENDHILL HOPWOOD.

News and Views

Mr. C. C. Paterson, O.B.E.

MR. CLIFFORD C. PATERSON, director of the Research Laboratories of the General Electric Co. Ltd., has had the honorary degree of doctor of science conferred on him by the University of Birmingham "in recognition of his many contributions and services to electrical science". Dr. Paterson, who is now fifty-seven years of age, was for sixteen years a member of the staff of the National Physical Laboratory, where he established and administered the Electrotechnics and Photometry Divisions of the Laboratory until 1918. He then accepted the task under Lord Hirst of initiating the G.E.C. Laboratories at Wembley. These have now grown so much in size and influence that they have a personnel of 500 and cover a floor area of about 170,000 sq. ft. Dr.

Paterson's activities have not been confined to the Wembley Laboratories. He was president of the Institution of Electrical Engineers in the year of the Faraday celebrations (1931). He has been president of the International Illumination Commission, the Illuminating Engineering Society, and this year of the Institute of Physics; he is also a vice-president of the Royal Institution and of the Royal Society of Arts. He has been Faraday lecturer of the Institution of Electrical Engineers, Huxley lecturer of the University of Birmingham, and is this year Guthrie lecturer of the Physical Society. Whilst Dr. Paterson's activities in engineering and science have covered a wide range, his chief personal contributions and scientific papers have been in the fields of light and lighting.

Palaeolithic Man in Brittany

IN view of recent reference to the fact that evidence of a Palaeolithic Age had not been found in Brittany (see *NATURE*, Aug. 21, p. 329), it is of interest to note that M. R. Mazères records in the current number of *L'Anthropologie* (47, 3-4) that he has found a number of flint implements of that period, when examining the quaternary deposits of the cliffs in the bay of St. Brieuc (Côte-du-Nord). The deposits include a lower and upper loess. Of these the lower, a gray loess attributed to the Riss glaciation, is ravined by interglacial deposits of marine origin, with an abundance of *Buccinum reticulatum*, and evidence of a superimposed raised beach at an altitude 8-9 metres, which would warrant an attribution to Mousterian, or Tyrrhenian II. Above this, and at times associated with traces of the raised beach, is the upper loess, showing evidence of two periods of deposition. In the earlier deposits of this phase were found a dozen flint implements of Mousterian facies, with flakes of diabase and other stone of the same technique in working, and the tooth of a reindeer. The use of stone other than flint is attributed to the scarcity of the latter material in the neighbourhood. The later deposits yielded two well-made carinated scrapers of flint of Middle Aurignacian type. In the same horizon, but at another site, were found a reindeer tooth and the tooth of one of the Bovidae. The attribution of the upper loess to Wurm I and Wurm II is thus confirmed by the character of the contained implements. M. Mazères points out that, modest as these finds are, they serve to indicate the existence of a palaeolithic culture in Brittany. This is now apparently recorded for the first time; but M. Mazères recalls that in 1926 Prof. Milon and the Abbé Leclerc found a mammoth tusk in the loess to the north of Pléneuf, near the location of the present finds, and with it were flints which have not been studied.

Recent Archaeological Excavations in Great Britain

THE continued examination of the neolithic barrow at Chilham, Kent, known as Julaber's Grave, which is in course of excavation by Mr. R. F. Jessup on behalf of the owner, Sir Edmund Davis (see *NATURE*, August 7, p. 228), has brought to light further evidence regarded as confirming local tradition. The occurrence, among other finds, of equine bones and teeth (*The Times*, August 16) seems to afford some foundation for the belief that the remains of one hundred horses and one hundred men were buried in the barrow. An examination of the teeth, however, suggests that the horses may have been buried there at various times in a period of centuries. Excavation has ceased for this season, but will be resumed in July next. A five weeks' season of excavation at Milber Camp, Newton Abbot, conducted by the Devon Archaeological Society under the direction of Mr. F. C. Cottrill, leads to the conclusion that the camp was constructed in the last century before the Roman invasion for the purpose, it would appear, of commanding the junction of two important tracks, and that it was abandoned when the Romans built

a bridge over the river at Teignmouth. Among the finds brought to light in the course of the excavation were a polished stone axe, a sling stone, decorated spindle whorls and pottery. The site was reoccupied in the Middle Ages, probably by shepherds.

Two food vessels, attributed to a date of about 2000 B.C., are reported to have been unearthed by workmen employed in the Fife Redstone Quarry, Belmullo, near St. Andrews. They were found at a depth of three feet below the surface on the side of a hill. They stand about six inches high, have a diameter of about four inches, and are ornamented with a decoration of cord impressions. Operations at the Mease Lake Village, near Glastonbury, in Somerset, were resumed for the current season on August 23. Dr. A. Bulleid and Mr. H. St. George Gray are again in charge of the excavations, acting on behalf of the Somerset Archaeological and Natural History Society. The work of investigation this year will be confined to the central portion of the main group of dwellings of the East Village, upon which operations have been concentrated for the last four years. Until four years ago the West Village had been the principal site of excavation. A monograph has been prepared and is about to be published on the results obtained in the period between 1910, when the systematic examination of this site began after the close of investigations at the Lake Village of Glastonbury, and 1933, when excavation on the West Village was brought to an end. About half this part of the site had then been investigated. The excavations this year will be carried on for a period of four weeks.

Excavations on the Roman Site at Wroxeter

THE Committee of the Wroxeter Excavation Fund has issued an appeal for funds to enable it to continue excavation on the Roman site of Uriconium. Previous investigations have covered about ten acres of a total area of 200 acres. Excavations were undertaken last year on a small scale by the Shropshire Archaeological Society. It is proposed to continue these excavations. Generous assistance has been given by Sir Charles Marston, who is president of the Shropshire Archaeological Society, and subscriptions have been promised by the Society of Antiquaries of London and All Souls' College, Oxford. The excavation again will be directed by Miss Kathleen Kenyon, who was in charge last year. The objects of this season's operations will be the further examination of the so-called Baths building by excavation on its north side, and the identification and excavation of the east gate of the city. It is anticipated that these investigations will throw light on three important problems: the history of the defences, the plan of the city, and the line of Watling Street, which is here in dispute. Donations should be addressed to the secretary of the Fund, Mr. A. E. Cooper, 28 Claremont Hill, Shrewsbury.

Industrial Research in India

THE report of the Industrial Research Bureau, Government of India, for 1936-37, covers the work of the Industrial Research Council and the research

work at the Government Test House as well as the work of the Bureau (Delhi: Manager of Publications, 1937. 14 annas; 1s. 6d.) The Industrial Research Council is an advisory body, consisting of representatives and non-official nominees of the central, provincial and leading State Governments, which meets once a year to discuss policy in the co-ordination and development of research. Programmes for road research have been approved by the Council, and the development of the manufacture of casein plastics has been considered both by the Council and by the Bureau. Industrial standardization and the compilation of a list of researches in progress or contemplated in industrial laboratories are also receiving attention, and a number of prizes have been awarded by the Council for papers bearing on industrial development. The research branch of the Government Test House which deals with the research programmes suggested by the Council and other problems referred to the Bureau has completed a preliminary investigation on the characteristics which affect the setting of red lead paint. For accelerated weathering tests on various paints the weatherometer, modified to give test conditions approximately to outside weather conditions at Alipore, has been used.

SPECIAL apparatus has also been developed in India for accelerated life tests on dry cells and considerable attention has been devoted to the use of vegetable oils for internal combustion engines. A process has been developed for rendering castor oil miscible with mineral oils of known suitability for use in such engines, and the effects of various anti-oxidants have been investigated. Steady progress has been made with the work of modifying the Morris and Lister engines and of equipping them with accessories to render the operating conditions fully controllable. Another section has been responsible for important investigations on the properties of petrol-benzole mixtures and the effect of changes in the composition of the benzole. A number of investigations on sand, lime, surkhi, clay, etc., have been initiated. Good progress has been made with the design of the equipment for the proposed road test track at Calcutta. Separate chapters in the report deal with work on glass and on oils and soaps, the former including the improvement of glass furnaces and a survey of glass-making materials.

Research in the Iron and Steel Industry

At the request of the Board of Trade, the Import Duties Advisory Committee has conducted an inquiry into "The Present Position and Future Development of the Iron and Steel Industry", and its report, which is full of interest, has now been issued (Cmd. 5507. London: H.M. Stationery Office, 1937. 2s. net). The report is essentially concerned with economic conditions, but its authors recognize that both the present and the future of the industry are closely bound up with scientific control and research. They express their satisfaction with the provision made for research and their hope that it will be further

extended in the future. The total industrial subscription to the Iron and Steel Industrial Research Council for 1936-37 is estimated as £30,000. As the capital of the concerns estimated to be responsible for 86 per cent of the country's output of steel in 1936 is given as £126.7 millions, this cannot be considered an excessive allowance. Several of the large steel concerns have their own research laboratories, involving a considerable expenditure, and these have actively collaborated in the investigations of the Council, thus making an indirect contribution. Full particulars of the research organization were furnished to the Committee by the Department of Scientific and Industrial Research in writing, but the seventy-three witnesses examined orally did not include a scientific metallurgist or a director of a research laboratory, and one would have welcomed a fuller appreciation in the report of the fact that the economies to be effected by scientific improvements—as, for example, in the field of refractories—are as important as the improvements in organization to which the report, thorough as it is, is almost entirely devoted.

Far Eastern Conference on Rural Hygiene

A CONFERENCE for Far Eastern countries on this subject was opened on August 3 by the Governor-General at Bandoeng, Java. This Conference was arranged by the League of Nations Health Organisation under the presidency of Dr. T. Offringa, director of the Netherlands Indies Public Health Service, with Dr. J. Rajchman, medical director of the League Health Committee, as secretary, assisted by Dr. C. L. Park, director of the Eastern Bureau of the Health Organisation. The Conference is meeting in five sections, in which the following subjects will be discussed: (1) health and medical services: the advantages and disadvantages of training 'semi-qualified' or assistant doctors to assist the qualified medical staff, and possible alternatives; (2) rural reconstruction and collaboration of the population, with the view of improving conditions of life in rural districts, a policy favoured by the Government of India and other countries; (3) sanitation and sanitary engineering, including housing, water supply, latrines, refuse disposal and fly control; (4) nutrition, a subject of importance in the East, for it has been estimated that 75 per cent of the population of Asiatic countries exist on a diet below the standards fixed by European science; (5) measures necessary to combat specific diseases, such as malaria, plague, tuberculosis, hookworm infection, yaws and leprosy, and mental diseases; also drug addiction.

The Science Museum

BEYOND the usual statistical information regarding the number of visitors and attendances at lectures, notes on special exhibitions, on acquisitions and the progress of the five main divisions of the Museum, the annual report of the Advisory Council of the Science Museum for 1936 is of especial interest as it contains a review of the growth and activities

of the Library, which is being developed as a National Library of Science. During the year, the Library was used by 22,000 readers, while the issues on loan of books and periodicals to Government departments, scientific and technical societies, colleges, etc., was 21,000. The Library receives more than 9,000 current periodicals and the contents of these are all indexed, references to these and to other matters now running into millions. There are about 250,000 books in the Library. "The two main functions of the Library," the report says, "may broadly be stated as the acquiring of documents and making them readily available", the latter consisting of cataloguing the volumes, maintaining indexes of their contents, provision of the volumes to readers, loan service, supply of bibliographies, supply of photostat copies, and Library publications. There have been many valuable additions to the collections in the Museum, and during the year under review special exhibitions were arranged illustrating the progress of research at very low temperatures, the scientific aspects of smoke pollution of the atmosphere and the developments in electric illumination.

Overhead Costs in Business Management

ONE of the most difficult tasks for a business management, whether the concern be large or small, is the adequate control of overhead costs. The usual classification of overhead expenses into salaries, rent, rates and taxes, legal expenses or the like is quite inadequate, because responsibilities cannot be tied up with the expenditure on these items, and generally there is no method of measuring the value obtained from the expenditure. In a valuable and thought-provoking report entitled "The Control of Overheads" (Mansfield House, 376 Strand, W.C.2. 5s.), prepared by a committee of the Management Research Groups, the subject is examined with the aim of securing effective control through localization of responsibility. To secure this, the report recommends the division of all overhead expenditure into a series of functions or services, each of which would be in charge of one person, thus permitting the fixation of responsibility. In order to assess the value of the work done by each section of the organization, its cost must be related to the volume of the work done and to the value or quality of that work; and for this purpose various ratios or 'yard sticks' are suggested in the report. The essential requirement is that responsibility for functional costs should be invested in persons, and to ensure that personnel shall cover each of the functions, it is most desirable that an organization chart should be constructed. Budgetary control is an excellent method of reviewing expenses in advance and making comparisons immediately results are available. Costs, however, may be rendered useless as a means of measuring efficiency because of plant working under capacity owing to insufficiency of orders. The report, therefore, recommends that the costs be 'purified' of the cost of idle plant by the abstracting and debiting of all such expenses to a non-productive account, which is carried straight on the trading account.

Economics of Wages and Price Levels

IN an address before the Economic Reform Club, London, on June 30, entitled "The Economic Reforms Required for Lasting Prosperity and Peace" which has now been issued in pamphlet form (Economic Reform Club, 61 Great Cumberland Place, London, W.1. 9d.), Mr. A. G. McGregor stresses the supreme importance of reform in wages regulation in securing a steady purchasing power of the pound. He urges that the method of adjusting wages by industrial dispute should be abolished and replaced by direct government control to adjust wages in accordance with the price level. This would in the first instance involve raising wages and salaries to a level which would bring consuming power in step with productive power, and thereafter the wages board would maintain the proper relation between wages and price level. He stresses the point that bankers should be relieved of all responsibility over the general price level and outlines the functions of a rational banking policy designed to accommodate industry and commerce with the necessary funds but under rules which eliminate any monetary influence on the price level. He contends that if wages and salaries are controlled in the way indicated so as to secure a satisfactory equilibrium between consuming power and productive power, economic liberty is no more affected than individual freedom in general by the ordinary government responsibility for maintaining law and order, and also that the higher wages and internal consuming power would assist the export trade.

Purchasing Power with a Managed Gold Standard

IN a pamphlet entitled "A Managed Gold Standard" (W. Haffer and Sons, Ltd., Cambridge), E. A. Meyer urges that unemployment and economic distress are due to lack of purchasing power. The State's lack of purchasing power has necessitated higher taxes, which have further decreased the citizen's purchasing power. This lack of purchasing power is due to lack of counters, or money, used for exchanging one man's labour for another's, caused by the inability of an inflexible money standard to keep pace with a continuous rise in prices. He advocates accordingly a managed gold standard based on the monopolization by the State of the note issuing bank of the standard (gold), and the fixation of the standard's money value by an international commission which should revise this value periodically according to the need of the world's productive ability to ensure the standard's flexibility. The managed standard will instantly increase the purchasing power of the State by increasing its right to issue counters without risk of devaluation, and this increased purchasing power by permitting decreased taxation will increase the purchasing power of the citizen as well as thus stimulating industrial and commercial prosperity. Unemployment will be further diminished or eliminated by the increased ability of the State to initiate public works. The managed gold standard could be introduced if a few countries only agreed to do so, since other countries would be bound to follow.

The Television Cable

In the Engineering Supplement to the *Siemens Magazine* of June, Mr. A. Rosen describes the London television cable which joins the Alexandra Palace studio to Broadcasting House and goes thence to the Whitehall Telephone Exchange. Success is being achieved and provincial cities are looking forward to having broadcast television services. It is probable that eventually there will be a network of television cables interconnecting the studios and transmitters throughout the country, similar to the grid of the programme circuits which now exists for sound broadcasting. Television is analogous to telephony. In telephony the voice sounds are converted by the microphone into equivalent alternating currents; these are transmitted to the receiving loud-speaker, where they are converted back to the voice sounds. Similarly the visual image is converted by the television camera into equivalent electric currents which are carried to the receiver where the cathode ray tube converts them back to the visual image. In both cases the transmission between sender and receiver can be effected over a metallic circuit, or by a radio link or by a combination of the two methods.

THE chief points of difference between the two transmissions concern the band of frequencies which have to be transmitted. In telephony, for music it suffices to transmit currents of frequency lying between 50 and 10,000 cycles to get excellent results. The television camera generates a much wider band of frequencies. In the Marconi-E.M.I. system, the frequencies range from zero to more than two million cycles. This necessitates the use of a correspondingly high carrier frequency for radio television transmission. The B.B.C. is to be congratulated on its notable achievement in televising the Coronation procession. This was the first successful high-definition relay in the world. The E.M.I. and Siemens gave valuable assistance to the B.B.C. in carrying out this enterprise. The author states that for trustworthy transmission between points more than 25 miles apart cables are necessary. Radio links also are liable to be affected by 'man-made' disturbances such as the radiations produced by the ignition systems of motor cars.

The Electrification of the Rigi Railway

It is now sixty-six years ago since the first rack railway in Europe, the Rigi railway, between Vitznau on the Lake of Lucerne and the top of the Rigi, was opened. It will be electrified in the autumn of the present year and will be brought into line with the latest modern requirements. The new motor-coaches will be light and comfortable, and the increase in speed will shorten the trip considerably. Fewer employees will be required as the preliminary work done in starting up the steam locomotives will be done away with and because it is easier to supervise electric vehicles. One-man control also suffices in the motor-coaches. When peak track conditions occur some of the existing steam locomotives can be used, and these are kept as a useful stand-by. The

electric equipment of the motor-coaches will be built by Brown, Boveri and Co., Ltd., Baden, while the mechanical part and coachwork will be constructed by the Swiss Locomotive Works at Winterthur. Direct current will be used at a pressure of 1,500 volts and the average running speed will be about nine miles per hour. On the up-grade, the highest running speed is about eleven miles an hour and on the down-grade about seven miles an hour. The difference in altitude between the Vitznau and Rigi Kulm stations is about 4,300 feet, and the steepest gradient is 25 per cent. In the *Brown Boveri Review* of March, diagrams of the new coaches are shown. The braking devices comprise electric resistance braking as service brake on the down-grade and two hand brakes independent of one another and actuated by spindle from either driver cab. When the brake is applied on the up-grade it prevents the coach running backwards should the current fail. There is also an overspeed brake which operates on a brake drum on the motor and only acts on down-grade running. In emergencies it is put into action by a safety device.

The House-Rat in the United States

ALTHOUGH the black rat (*Rattus rattus*) still predominates in the southern States, particularly in Florida and the States bordering the Gulf of Mexico, throughout the States in the temperate zone it has been displaced by the brown rat (*Rattus norvegicus*), which appears to have been introduced about the beginning of the American Revolution, in 1775. Now the rat population is enormous—in Texas some years ago 153,720 rat tails were collected in six weeks; in Georgia, Alabama and Texas during the typhus fever control campaign in 1934, it was estimated that 7,500,000 rats were destroyed on 747,608 premises treated, or approximately two rats for every person living on the premises. The total economic damage done by these pests is enormous. In the course of one of its inquiries, the Biological Survey received 14,650 replies from farmers co-operating in rat campaigns, and the annual losses therein reported averaged \$5 dollars a farm, while a computation of the grand total of loss throughout the United States each year is 180 million dollars. In addition, rats are seriously concerned in the conveyance of certain diseases among human beings and domestic stock, and in an effort to arouse co-operative measures of rat-control, the U.S. Department of Agriculture has published an eighteen-page circular (No. 423, Jan. 1937) on "The House Rat".

Migrations of Salmon

At a meeting of the Washington Academy of Sciences held recently, a discussion on the homing migrations of salmon was opened by Prof. Henry B. Ward. According to a report by Science Service, of Washington, D.C., he said that the return of salmon, generation after generation, to their ancestral breeding grounds, is a response to definite stimuli, amongst which he regards temperature as being the most powerful. Swiftness of current has also some effect in guiding the fishes, although relative acidity of the water seems to have no influence. But if it be

admitted that salmon return to the streams where they were born—and there is much evidence supporting that view—it cannot be admitted that either the temperature of a particular stream or the swiftness of its current remains constant. It is difficult to understand, therefore, just how these variable factors can guide migrating salmon, not to a specially cold or swift stream, but to a particular stream the one outstanding character of which is that they were born there.

U.S. Zoological Expedition to Far East

A PARTY of scientific workers from Harvard and Johns Hopkins Universities has set out with the intention of making a survey of the birds and mammals of Siam, Borneo and Sumatra (Science Service, Washington, D.C.). The results should be of special significance, for the programme includes study of the social life of some of the most interesting of the higher monkeys. In the jungles of Siam, the habits of the gibbons will be observed for three or four months by Dr. Carpenter; other members of the expedition will carry out parallel observations in British North Borneo on orang-utans, gibbons and proboscis monkeys; while, later, in the mountains of northern Sumatra, orang-utans will be studied in the national park recently set aside by the Netherlands Government to protect this rapidly disappearing animal. It is expected that the study of the social habits of these creatures may throw light upon the problems of man's social and physical evolution.

Radio-Therapeutic Treatment of Cancer

THE Ministry of Health has issued an important publication on cancer treatment entitled "Cancer: Memorandum on Provision of Radio-Therapeutic Departments in General Hospitals", by Lieut.-Colonel Smallman (Reps. on Pub. Health and Med. Subjects, No. 79. London: H.M. Stationery Office. 9d. net). A principal reason for the preparation of this memorandum is the growing use of radium and X-rays in the treatment of cancer, in substitution for, or in conjunction with, surgery. As a result, hospitals in which cancer patients are treated need to be specially equipped and staffed for this part of their work. The memorandum emphasizes the importance of team work, and that the radio-therapeutic department should be in close touch not only with the surgical department, but also with other departments (gynaecological, pathological, etc.) provided by the hospital of which it should form an integral part. It concludes that a general hospital should contain some three hundred beds if it is to make reasonably full use of radiation treatment facilities. Plans are given for the lay-out of a radio-therapeutic department, the various features of which are explained in the text. The memorandum discusses how those hospitals which cannot provide full cancer treatment facilities can be enabled to make use of other hospitals in which full facilities exist. Appendixes contain the recommendations of the British X-Ray and Radium Protection Committee and of the Radium Commission on the care and custody of radium.

Physics at Harvard

THE volume of "Contributions" from the Physical Laboratories of Harvard University for 1935 is again of quarto form and consists of reprints without change of pagination, of fifty-seven memoirs by members of the staff, fellows and students which have appeared in scientific periodicals such as the *Physical Review*, the *Proceedings of the American Academy*, the *Review of Scientific Instruments*, during 1935 and the first two months of 1936. The quarto form allows the inclusion of the large double column pages of *Industrial and Engineering Chemistry*, but gives very wide margins to the single column pages of the *Proceedings of the Academy*. Work on the physical properties of materials at high hydrostatic pressure accounts for seven or eight of the memoirs, and special interest is attached to Prof. P. W. Bridgman's method of securing measurements at 50,000 atmospheres pressure in steel vessels which normally rupture at 20,000 atmospheres. Atomic physics accounts for about a dozen memoirs, of which that on the quantum theory of valence by Prof. Van Vleck and Dr. Sherman, a fellow of the National Research Council, reprinted from *Reviews of Modern Physics*, may be mentioned. The whole volume bears evidence to the active part Harvard is taking in the advance of knowledge.

Field Work of the Smithsonian Institution in 1936

THE preliminary survey of recent field work of the Smithsonian Institution ("Explorations and Field-Work of the Smithsonian Institution in 1936," Washington, D.C., 1937; pp. 100) covers nineteen investigations, beginning with Dr. G. C. Abbot's "Exploring Solar Power Possibilities" and including research in geology, paleontology, zoology, botany and anthropology, the last-named predominating with seven investigations, mostly archaeological. Of these last, Dr. Hrdlička's explorations of sites on Kodiak Island, Alaska, and the Aleutian Islands have attracted no little attention, not only on account of the exceptionally large number of antiquities brought back by this year's expedition, but also by the collection of mummified human remains from Kagamil. Dr. Henry B. Collins, jun., by his excavations at Bering Strait, has succeeded in determining beyond question the place of the Thule culture in the cultural succession at this gate of entry of man into the American continent—an important contribution to the Eskimo problem—and also has arrived at the conclusion that there is little hope of discovering any trace here of the passage of early man prior to the Eskimo, owing to physiographic changes. Further investigations by Dr. Frank H. Roberts, jun., on sites of the Folsom culture in Colorado and on a new site in Iowa discovered in 1935, the easternmost occurrence noted of the true Folsom stone point, have yielded new data bearing on the occurrence of this early type of the American stone age. It is now established that Folsom man was contemporary with the extinct camel, and also that he lived before, as well as at the same time as, the thick growth of vegetation which preceded the present condition of

aridity in the south-western area. This points to an antiquity even higher than that indicated by previous evidence.

Liverpool Naturalists' Field Club

THE seventy-sixth Annual Proceedings of the Liverpool Naturalists' Field Club, recently issued, covers the year 1936. The botanical notes include a summary by Mr. J. D. Massey of ninety new plant stations in the area recorded in the past four years since the compilation of Dr. Green's last "Flora of Liverpool", while Mr. W. S. Laverock, the botanical referee, describes the finding of deadly nightshade (*Atropa belladonna*) at Eastham, adder's tongue fern (*Ophioglossum vulgatum*) near the Manchester Ship Canal at Mount Manisty, young sycamore trees with variegated foliage at Irby woods, and other incidents of the field meetings of the year. The year's ornithological records, compiled by Mr. Eric Hardy, the ornithological referee, include a water-pipit, ruffs, a part-albino pied wagtail, curlew-sandpiper, little stint, greenshanks, green-sandpipers and a very late (November 28) yellow wagtail at Liverpool Sewage Farm, the latter (after a fog spell) a day later than the previous latest record in Britain; crossbills in the Ainsdale-Froshfield pinewoods in winter, a sculp wintering at the Botanic Park, Liverpool, puffins, fork-tailed petrels and mergansers in the Dee Estuary, a redwing summering in Knowsley Park and the nesting of the Canada goose and little grebe at Kirkby Dam, lesser black-backed gull and curlew at Simonswood, oyster-catcher and rock-pipit by the Ship Canal below Eastham, shoveller at Burton, grasshopper-warbler at Ince and Gayton in Wirral, and blackcap in Knowsley Park. The long-tailed duck is reported in full summer plumage feeding on crabs in West Kirby marine lake in mid-May. There are also the results of surveys carried out in the area for the British Trust for Ornithology, etc. The Committee reports an increase in membership during the year, the formation of a junior section, and an appeal for the Ornithological Fund.

Review of Agriculture

THE Royal Agricultural Society of England (16 Bedford Square, London, W.C.1) has published its ninety-seventh volume, which includes, as last year, the "Farmers' Guide to Agricultural Research". The latter consists of a review of research work in various branches of agriculture, each section being contributed by a recognized authority on the subject. The journal also contains a number of special articles on important questions such as housing the agricultural worker, labour, power and equipment in arable farming, the improvement of hill grazings and the technique of modern field experiments. On the animal side are articles dealing with the control of sheep ticks and systems of housing for pigs. The series on notable farm enterprises is continued, the Cambridge University Farm and Mr. Clyde Higgs's dairy farms being described in this number. The economics of farming are represented in an article on changes in beef imports before and after the Ottawa Agreement. The price of the journal is 15s.

British Scientific and Technical Books

A SELECT list of standard British scientific and technical books has been issued by the Association of Special Libraries and Information Bureaux. The list has been compiled at the request of the British Council and is planned as a guide in selecting books for a library. It is limited to about 300 works and is not a complete bibliography of the subjects covered, books out of print being omitted. Agriculture and medicine have been deliberately omitted, and the main purpose of the list is to assist in the choice of a collection of British scientific and technical books. Under each main section the books, so far as possible, are placed in a logical sequence of subjects, and it is intended that the ASLIB book list should provide a convenient means of keeping the select list up to date. The list contains a foreword by Sir William Bragg and an introduction by Sir Richard Gregory. The price of the list is 2s. to subscribers of the ASLIB book list and 2s. 6d. to non-subscribers.

Preliminary General Catalogue of Comets

VOL. 1, No. 4 of *Publications of the Kwasan Observatory* contains a catalogue of comets from the year 487 B.C. to the year A.D. 1936. The number of comets listed is 467, and in each case the best available orbit with its reference source is given. The present catalogue is the revision of a catalogue published in 1931 by Prof. Issai Yamamoto in the *Astronomical Yearbook of the Oriental Astronomical Association*, printed in Japanese. This revised edition of the catalogue by his son, Prof. A. S. Yamamoto, who contributes a preface in English, will be very useful to all students of cometary orbits. A more comprehensive general catalogue is in course of preparation by these authors.

Memorial to Sir Walter Morley Fletcher

AN account of the memorial to the late Sir Walter Morley Fletcher, secretary of the Medical Research Committee and Council in 1914-33, printed for the trustees of the memorial fund by the University Press, Oxford, has been issued to subscribers to the fund. It is illustrated with two plates, one of Miss Dora Clarke's posthumous portrait bust of Sir Walter Fletcher, photographed from the clay model, the other of a corner of the library of the National Institute for Medical Research with the finished bronze in position. After meeting the cost of this personal memorial, the balance of the fund is to be applied for a Walter Fletcher Memorial Laboratory at the Farm Laboratories of the National Institute at Mill Hill. The printed account contains appreciations of Sir Walter Fletcher by Prof. G. M. Trevelyan and Sir Gowland Hopkins.

Rehabilitation of Persons Injured by Accidents

THE Inter-Departmental Committee on the Rehabilitation of Persons injured by Accidents, set up jointly by the Home Office, Ministry of Health and Scottish Office, has issued an interim report (H.M. Stationery Office. 4d. net). This report deals particularly with the organization of "fracture clinics".

The object aimed at is the covering of the country with a network of services, for the most part attached to existing hospitals, and based upon a report issued by the British Medical Association in 1935. The need for such a service will be appreciated when it is stated that more than 201,000 new cases of fractures were treated at voluntary and municipal hospitals in Great Britain during 1935.

Science and the Life of the Community

At the meeting of the General Assembly of the International Council of Scientific Unions last May, a resolution from the Royal Amsterdam Academy of Sciences was adopted (with some modifications) for the appointment of a committee to examine various questions concerned with the practical application of scientific results in the life of the community. That committee has now been constituted as follows: Prof. J. N. Bronsted (Copenhagen), Prof. J. M. Burgers (Delft), Prof. S. Chapman (London), M. Establier (Paris), Prof. B. Nemeš (Prague), M. François Perrin (Paris) and Prof. F. J. M. Stratton (Cambridge).

Return of a Large Sunspot

THE leader sunspot of the extensive group, visible from July 22 until August 4, has returned to view, the following component having in the meantime disappeared. The area of this leader spot was about 1000 millionths of the sun's hemisphere on August 20, and on the following day, although the spot was not very far on the disk, it could be seen with the naked eye. The date of central meridian passage is August 25.3, and the sun's west limb will be reached on August 31. Since the spot is situated in fairly high latitude (33° north), its drift backwards in longitude is very marked as compared with the angular rotation of the standard meridian (Carrington's) used in computing sunspot positions and which is given by the mean of sunspots in solar latitude 15°–16° north and south.

The Night Sky in September

ON September 23 at 11^h U.T., the sun enters the sign Libra (the autumnal equinox). In the latitude of London, the night is then more than 4½ hours longer than at the time of the summer solstice. The moon is new on September 4 at 22.9^h and full (the Harvest Moon) on September 20 at 11.5^h. Conjunctions with the planets take place as follows: with Venus on Sept. 2 at 3^h; with Mercury on Sept. 6 at 5^h; with Mars on Sept. 12 at 18^h; with Jupiter on Sept. 15 at 6^h and with Saturn on Sept. 21 at 1^h. An occultation of the star ξ Sagittarii (magnitude 3.6) occurs on September 14, the disappearance being visible from Greenwich at 18^h 37.5^m. On September 24, Venus approaches the bright star Regulus. A close appulse of Mars to the 9th magnitude star C.D. 11856 will be visible from South Africa on September 7 at about 17.6^h U.T. During the month, Finlay's comet in the constellation Virgo continues to move southwards. The following ephemeris is given by Dr. A. D. Maxwell's orbit of the comet:

	R.A.	Dec.
Aug. 31	14 ^h 6.5 ^m	+ 6° 3'
Sept. 4	8.6	+ 1 48
8	10.2	— 1 37
12	11.3	— 4 24
16	12.3	— 6 45
20	13.2	— 8 45
24	14.0	— 10 30
28	14.8	— 12 3
Oct. 2	15.7	— 13 27

There is a faint comet, discovered by Hubble on August 4, in the south-east region of Aquarius. Positions for Encke's comet (passing from Aries to Triangulum) and for comet Grigg-Skjellerup (passing from Ophiuchus to Serpens) will be found in the "B.A.A. Handbook". β Persei (Algol) is now becoming well placed in the late evening for observing the variability of its brightness. The change in light is best seen about 1.5 hours before and after the following times: Sept. 5^d 03.5^h, Sept. 8^d 00.3^h, Sept. 10^d 21.1^h, Sept. 28^d 02.0^h and Sept. 30^d 22.8^h. Meteors, the radiant of which is a little south-east of α Persei, may be looked for from September 7 until 15. The night sky during this month offers an unequalled range of various objects within reach of binoculars or small telescopes. In the middle of the month about 21^h, the cluster of the Pleiades will be seen rising in the north-east. (All times are given in U.T.: add 1 hour to convert to Summer Time.)

Announcements

THE bicentenary of the birth of Luigi Galvani will be celebrated on October 18–20 by the town and University of Bologna and the Italian Society of Physics.

DR. MAX WESTENHÖFER, professor of general pathology and pathological anatomy in the University of Berlin, has been elected an honorary member of the Medical Association of Kinesiology at Buenos Aires.

DR. WERNER KUHN, extraordinary professor of physical chemistry at Karlsruhe, has been appointed full professor at Kiel in succession to Prof. Schwarz, who has been transferred to the chair of chemistry at Königsberg.

IN the famous Bialowieza National Park in Poland, a census of the game animals was carried out during the winter 1936–37, and the following count was made: stags 35, deer 78, wild boar 50, wolf 4 (temporary immigrants), lynx 7, fox 8, badger 10, otter 4, marten 5, polecat 19, hare about 30, woodgrouse 30 (*Kwartalny Biuletyn Informacyjny*, 29; 1937).

AN informal meeting to discuss how far scientific workers can help towards the planning of the land of Great Britain, which is one of the important topics of discussion this year at the meeting of the British Association, will be held at Nottingham by the Research Co-ordination Committee (LePlay House, 35 Gordon Square, W.C.1) at the suggestion of the Association of Scientific Workers.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 366.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Biological Effects of the Rays produced by a Cyclotron

BIOLOGICAL effects of neutron-rays from a cyclotron have been reported, on the change of blood pictures in living rats by Lawrence and Lawrence¹, on the retardation of the germination of wheat seedlings by Zirkle and Aebersold², and on the fatal dose of the sarcoma 180 by Lawrence, Aebersold and Lawrence³. They compared the effects of fast neutrons with those of hard X-rays, and found that neutrons are, in fact, biologically, much more effective than in the case of X-rays.

Apart from these questions of the action of neutrons, we have been engaged in making experiments on histological changes in the organs of a mouse, irradiated with rays produced by bombarding a beryllium target with 2.8 MeV. deuterons from the cyclotron in this Institute.

Healthy male mice weighing 13-17 gm. were chosen for use because of their small size, which made irradiation possible in the limited space available in the cyclotron. A glass cylinder, 2 mm. in wall thickness, 46 mm. in diameter, and 106 mm. in length, was divided into two parts by a glass plate inserted along the axis, one animal being put in each of the partitions. The cylinder was placed in the observation chamber of the cyclotron, and the two mice were irradiated simultaneously under the same conditions. The animals were kept at an equal mean distance of about 8 cm. from the beryllium target. The irradiation was continued for four hours with mean deuteron current of 0.4 microampere.

FIG. 1.

(a) IRRADIATED SPLEEN; (b) NON-IRRADIATED SPLEEN.

As was shown in the laboratory of one of us, histological change of the spleen in the rat, irradiated with X-rays, can be observed best about ten hours after the beginning of irradiation⁴.

Therefore ten hours after the beginning of irradiation the animal was dissected; the spleen and testes

were taken out, the former being fixed in Helly solution and stained with hamatoxylin and eosin, while the latter was fixed in Champy solution and stained with Heidenhain's iron-hamatoxylin as usual.

Fig. 1a shows a follicle of the spleen in the irradiated animal, and Fig. 1b the same part of the non-

FIG. 2.

(a) IRRADIATED TESTIS; (b) NON-IRRADIATED TESTIS.

irradiated one; in the former, one can observe the remarkable decrease in the number of lymphocytes. Moreover, a large number of strongly stained dots in the same picture shows the destroyed particles.

In testicles, cells in the various stages of the spermatogenesis are more or less affected and destroyed, but interstitial cells, Sertoli's cells and spermatozoa are relatively intact. Further, one can observe in Fig. 2a that there is a diminution in radiosensitivity in passing through the various stages from spermatogonia to spermatozoa.

In conclusion, our thanks are due to Prof. S. Nishikawa and Dr. Y. Nishina for their interest in this work, to Mr. T. Yasaki and Mr. S. Watanabe for their assistance in the physical work, and to Dr. W. Nakahara for his hospitality in keeping our mice. We wish to thank the Japan Wireless Telegraph Company for the electromagnet and other equipments used for the cyclotron, and Mitsui Ho-onkwa Foundation and Tokyo Electric Light Company for financial support.

The Magnetic Field acting upon Neutrons inside Magnetized Iron

F. Bloch¹ has recently discussed the nature of the magnetic forces between electron and neutron and suggested a quantitative investigation of the magnetic scattering of slow neutrons. We have tried an alternative way of getting some information on these forces by studying the precession of slow neutrons inside magnetized iron, in order to decide whether the magnetic field H or the magnetic induction $B = (1 + 4\pi\kappa) \cdot H$ (κ being the susceptibility) determines the angle of precession².

In two previous letters³, evidence has been given of the precession of polarized slow neutrons passing through a magnetic field which is perpendicular to the direction of polarization. In consequence of the inhomogeneity of the thermal neutrons (C-neutrons) this precession leads to depolarization, the slower neutrons precessing more because they stay longer in the field. Polarized C-neutrons originating from paraffin cooled down to 90° K. should be practically depolarized after passing through 7 mm. of a field of 35 gauss. On the other hand, a field of 2.8 gauss along the same path will give an average precession angle of about 15° only and very little depolarization of the neutrons.

In our experiment, C-neutrons at 90° K. were allowed to pass through an iron polarizer and an antiparallel iron analyser, both magnetized to 14,000 gauss. The stray field outside those two iron bars was less than one gauss. A long coil was interposed between polarizer and analyser, its axis, the fields in the iron bars and the neutron beam being mutually perpendicular. The path of the beam within the coil was 7 mm. Currents producing 2.8 or 35 gauss inside the coil were switched on alternately. Taking more than 600,000 counts with a boron chamber (50 per cent of which were due to C-neutrons) we obtained (0.83 ± 0.26) per cent more counts with 35 gauss in the coil than with 2.8 gauss. This is the order of magnitude to be expected for the polarization effect according to our previous experiments.

An iron sheet of 0.15 mm. thickness was then placed inside the coil and the magnetic circuit was closed by connecting the ends of the sheet by means of an iron yoke. Another 600,000 counts were taken using the same currents as before. The difference between the number of counts with the high and the low field was only (-0.05 ± 0.24) per cent this time. It is seen that the polarization effect had disappeared.

We conclude from this experiment that the lower field is sufficient to depolarize the neutron beam entirely when the iron sheet is interposed. Since the path of the neutrons within the iron sheet (where depolarization must have occurred) was only 0.15 mm., the precession of the neutrons inside the iron has to be accounted for by an 'effective field' of ~ 600 gauss or more. The field strength H in the iron was 2.8 gauss only, the induction B was ~ 15,000 gauss; hence B , or at least $0.03 B$, must have acted upon the neutrons inside the iron.

The Initial Stages of Glycolysis in Muscle Extracts

We have already made a preliminary report¹ on the preparation from rabbit muscle, by a method involving repeated extraction with phosphate solution, of solutions of the glycolytic enzyme system, which appear to be more free from associated co-enzymes than are extracts prepared by other methods. The extracts convert starch to lactic acid in the presence of muscle *Kochsäft*, but do not do so in the presence of adenosine triphosphate, magnesium ions, cozymase and a trace of hexose diphosphate; an account of their properties, with the evidence of a participation of a new co-enzyme, will shortly be given in detail elsewhere.

In view of the current interest in the earliest stages of the transformation of polysaccharide in muscle extracts², we should like to direct attention to the behaviour of the extracts referred to above, in the presence of the co-enzymes, namely, adenosine triphosphate and magnesium ions, which have been regarded by most workers as effecting the initial phosphorylation in the chain of reactions. The points of interest are as follows:

(1) When magnesium ions alone have been added as co-enzyme, no esterification of phosphoric acid has ever been observed.

(2) When in addition to magnesium ions adenosine triphosphate is also present, rapid esterification takes place, and the ester formed consists at first wholly of an easily hydrolysable ester with the properties of the hexose-1-monophosphoric acid recently described by Cori and Cori³. In the later stages of the incubation the total amount of esterification increases more slowly and the easily hydrolysable ester is gradually converted into hexose-6-monophosphate. No other ester appears to be formed under these conditions.

(3) The rate of formation of the easily hydrolysable ester is roughly the same over a range of adenosine triphosphate concentrations from M/1,000 to M/10,000, is slightly less with M/50,000 and reduced to about one quarter with M/200,000 adenosine triphosphate. The amount of adenosine triphosphate required is therefore much less than that necessary for glycolysis as a whole to take place with optimal speed, and the amount of ester formed is far in excess of that which could be formed by simple transference of phosphate from the added adenosine triphosphate to the starch. If the mechanism were of this kind, continuous rephosphorylation of adenosine diphosphate or adenylic acid would have to take place, and no means of bringing this about seems to be present. No lactic or pyruvic acid is formed, so that the possibility of rephosphorylation from phosphopyruvic acid is ruled out. Adenylic acid itself brings about no esterification.

(4) The conversion of the hexose-1-monophosphate into hexose-6-monophosphate is much accelerated by the addition of a trace of hexose diphosphate.

The results described above are not in agreement with those reported from Parnas's laboratory⁴, where esterification in the absence of any added co-enzyme was observed, or with those of Lehmann and Needham⁵, who were able to confirm the findings of the above-mentioned school. The possibility that starch behaves differently from glycogen in this respect is being investigated. But since an easily measurable esterification is produced even by

M/200,000 adenosine triphosphate, one hesitates, in view of the well-known difficulty of eliminating co-enzyme completely from the enzyme system, to accept the evidence for esterification without co-enzymic intervention which has so far been provided.

Growth Factors for *Phycomyces*

DURING the last three years, Schopfer has published several papers¹ showing that vitamin B₁ is a growth factor for *Phycomyces*. This mould can now be grown on a synthetic medium composed of glucose, asparagine, inorganic salts and the vitamin. During the last two years, he has described² an alternative growth factor ('MP') which differs from the vitamin in being resistant to heat (128° C. for 20 hours causes only 75 per cent loss of activity) and resistant to alkali; it is oxidized by hydrogen peroxide.

Knight^{3,4} has shown that his growth factor for *Staphylococcus* consists of three parts, two being the pyrimidine (I) and thiazole (II) components of vitamin B₁ (III), and the third being nicotinic acid or its amide. Very recently Schopfer and Jung⁵ have stated that vitamin B₁ can be replaced as a growth factor for *Phycomyces* by the pyrimidine and thiazole components.

Through the kindness of Dr. Todd, I had also been able to test four synthetic compounds (I, II, IV and V) as growth factors for *Phycomyces*. On a medium composed of glucose, asparagine and inorganic salts, no growth is obtained when these four compounds are added singly. But I and II together give a very large growth (cf. Schopfer and Jung), IV and II a

fair growth, while V and II give no growth. Further, a neutral solution of vitamin B₁, autoclaved for two hours at 125° C., still acts as growth factor for *Phycomyces*, although the compound is destroyed. The activity of compounds I and IV is not destroyed by this treatment, even in presence of N/10 NaOH; hydrogen peroxide, however, destroys the activity. This supports Schopfer's suggestion that his factor 'MP' consists of degradation products of vitamin B₁. There is no doubt that vitamin B₁ itself, as well as its constituents, is a growth factor, since a solution sterilized by filtration through glass instead of by autoclaving remains active. Vitamin B₁ diphosphate ('co-carboxylase' of Lohmann), which was kindly supplied by Prof. Lohmann, is about as active as the vitamin itself.

Constituents of Vitamin E Concentrates from Rice- and Wheat-Germ Oils

THE pioneer work of Evans and his collaborators on the anti-sterility factor (vitamin E) has culminated in the isolation from the unsaponifiable fraction of wheat-germ¹ and cotton-seed² oils of three apparently isomeric oily alcohols α -, β - and γ -tocopherol of approximate formula C₅₅H₁₀₂O, all of which show high vitamin E activity. The use of the unsaponifiable fraction of rice-germ oil as a source of vitamin E was advocated by Kimm³, who later⁴ prepared from a purified concentrate a β -naphthoate, m.p. 156°, which yielded on hydrolysis a product alleged to have very high vitamin E activity.

By acylation of purified concentrates from the unsaponifiable portion of rice-germ oil with *p*-nitrobenzoyl chloride or β -naphthoyl chloride we obtained a complex mixture of oily and crystalline esters. The crystalline esters on separation and hydrolysis yielded three apparently homogeneous crystalline isomeric alcohols of formula C₅₅H₁₀₂O, (a) m.p. 121°–122°, (b) m.p. 113°–114° and (c) m.p. 119°–120°. The alcohol (c) yields a β -naphthoate corresponding in its properties to that of Kimm's active material; but like (a) and (b) it is devoid of vitamin E activity. Of these alcohols, (a) may be polyterpenoid in nature but (b) and (c) are certainly akin to the sterols, being similar in their properties to the tritosterols obtained by Karrer and Salomon⁵ from wheat-germ oil concentrates. In a parallel investigation of wheat-germ oil we isolated in similar fashion β -amyrin and two isomeric alcohols C₅₅H₁₀₂O of the tritosterol type, (d) m.p. 113°–114° and (e) m.p. 175°; of these (d) was also obtained by Karrer and Salomon. Neither (d) nor (e) possessed vitamin E activity.

The purified oils remaining after removal of these crystalline alcohols from both rice and wheat concentrates had a high biological activity, and gave, on thermal decomposition, considerable quantities of durohydroquinone C₁₄H₁₄O₂, which Fernholz⁶ obtained by similar treatment of pure α -tocopherol. On treating the oil from the wheat concentrate with cyanic acid in benzene, a mixture of allophanates

was obtained from which the products described by Evans, Emerson and Emerson¹ could be isolated, in addition to a crystalline allophanate, m.p. 70°, which has not yet been examined biologically.

The above purified oil from the rice concentrate deposited on standing a crystalline substance, m.p. 73°, which appears to be an aliphatic mono-unsaturated alcohol containing approximately 20 carbon atoms. After removal of this alcohol, the oil on saturation with cyanic acid in benzene solution gave a complex mixture of substances from which a small amount of an allophanate, m.p. 135°–138°, having the properties of β -tocopheryl allophanate², could be isolated together with a larger quantity of an allophanate, m.p. 195°–200°; the parent alcohol of the latter substance is being tested biologically.

In view of the formula of the tocopherols and the probability that they may represent mono-alkyl ethers of durohydroquimone³, the occurrence in active rice-germ oil concentrates of the alcohol m.p. 73° may be of some significance. The work on the structure of these various compounds, of which fuller details will be published elsewhere, is being continued.

Para-Cresol from the Urine of Pregnant Mares

Burrows, Cook *et al.*¹ have recently isolated *p*-cresol, along with certain ketones of the sterol group, from the urine of a man with a malignant tumour of the adrenal cortex. The urine (30 l.) was submitted to an initial hydrolysis by boiling with hydrochloric acid, and 0.75 gm. of *p*-cresol was isolated from the non-ketonic phenol fraction.

It should be recorded that in this Laboratory a similar observation has been made in regard to the urine of pregnant mares. Approximately 110 gm. of pure *p*-cresol, containing no detectable trace of *o*- or *m*-isomeride, was obtained from 400 gallons of mares' urine, which had been submitted to hydrolysis—a considerably higher proportion than that reported by Burrows, Cook *et al.* for a pathological specimen of human male urine. The significance of this finding is not yet apparent.

Artificial Release of Crossing-over in Meiosis and Mitosis

THE experiments with artificial production of crossing-over described below belong to a new series which were finished in the spring of this year; they enable us to carry our analysis much further and bring out a series of facts which are entirely new. The following are the main conclusions drawn from this work:

1. (a) X-ray treatment of *Drosophila melanogaster* males induces not only spermatogonial, but also meiotic crossing-over.

(b) Histological examination of irradiated testes revealed that the early spermatocytes of the first order possess the greatest susceptibility to treatment, whereas the spermatogonia, though also affected, react to a much less extent.

2. (a) The mitotic origin of spermatogonial crossing-over induced by X-rays in *Drosophila melanogaster* has been definitely established.

(b) The presence of inversions lowers somewhat the frequency of spermatogonial crossing-over throughout the non-inverted region of chromosome III. This proves that there is a similarity between regular meiotic and induced mitotic crossing-over.

(c) The frequency of spermatogonial crossing-over is extremely high in the central region (which carries the spindle fibre) of chromosome III. In the remaining regions of the chromosomes there is a closer correspondence with the cytological map than in the case of the normal meiotic crossing-over in females.

(d) The frequency of induced crossing-over is higher for later than for earlier spermatogonial stages.

(e) The frequency of spermatogonial crossing-over is not proportional to the X-ray dose (a comparison at 1,000 r. and 4,000 r. shows a frequency greater than fourfold in the latter case).

3. (a) No oögonial crossing-over was released in female larvae of *Drosophila melanogaster* with a treatment of 2,000 r.

(b) The *Oy* females used in this experiment

$\frac{b}{cn}$

showed nevertheless a statistically significant increase in crossing-over between 'b' and 'cn'. Since only the gonial stages were irradiated, this result must be taken to mean that there exists an after-effect of the treatment on crossing-over.

4. (a) Contrary to the current point of view, which excludes the possibility of crossing-over in the late oocyte of *Drosophila melanogaster*, we were successful in inducing interchange at that stage; this type of interchange we designate as late meiotic crossing-over.

(b) This fact raises certain difficulties for Darlington's and Belling's points of view on the mechanism of crossing-over, whereas it favours the interpretation offered by Sax.

From the above summarized results we may draw the following general conclusions:

(1) Crossing-over is a feature to some extent inherent in both meiosis and mitosis.

(2) The absence of regular crossing-over in the gonial stages of gametogenesis in *Drosophila melanogaster* can be explained by the disadvantages somatic crossing-over would offer; the suppression of crossing-over in the soma means its suppression in mitosis and also in the gonial cells.

(3) The hypothesis of Haldane and Huxley, which is based on the disadvantages that crossing-over would offer in the heterogametic sex, does not sufficiently substantiate the nearly complete absence of normal crossing-over in meiosis of *Drosophila melanogaster* males.

A detailed account of the work will appear in Russian (with an extensive German summary) in the *Biologicheskij Zhurnal*.

Cobalt, and Sheep Diseases

IN New Zealand, Askew and his co-workers have shown that cobalt plays a vital part in the healthy life of sheep and that small supplements of cobalt salts will cure sheep suffering from a type of anaemia. Sheep on Dartmoor are liable to a disease very similar in symptoms to those described by the New Zealand workers, and the usual practice of farmers is to send their flocks to lowland pastures in the autumn for two or three months.

Analyses of the cobalt content of the soils from moorland pastures on which sheep suffer and from lowland pastures on which sheep have been known to recover give striking differences which are statistically significant:

Moorland soils on which sheep suffer have a mean cobalt contents of 3.9 parts per million; lowland soils on which sheep recover, 16.7 parts per million.

The figure for the sickness soils is higher than that given by Kidson¹ for corresponding soils in New Zealand, where it was found that sickness was associated with soils having a cobalt content of two parts per million. In the Dartmoor district this figure would be about four parts per million, although occasionally samples have a slightly higher content.

Analyses of pastures show that those in the sickness areas have a mean content of 0.20 part per million cobalt and those in the recovery areas 0.45 part per million.

An examination of soil and pasture composition is in progress, and the relationship of these to the incidence of disease is being studied.

Effect of Occluded Hydrogen on the Rigidity of Metals

AN investigation of the above effect was prompted by an inquiry into the nature of the earth's interior. The existence of a very definite core of radius half that of the earth seems established beyond reasonable doubt by seismology. The nature of this core is puzzling. Tidal phenomena and the Eulerian nutation demand that this core be less rigid than the crust. The noticeable absence of the shear wave on earthquake records of quakes sufficiently distant for the waves to pass through the core (and this, despite the presence of very pronounced compressional waves of the same quake on the record), was taken to mean that the core could not transmit a shear wave. A liquid core was therefore quite generally held to fit in with all known phenomena. However, during the past few years several seismic investigators, after exhaustive study of records, feel reasonably sure that the shear wave does pass through the core, but with greatly diminished energy. This would seem to imply either that a fluid under high pressure can transmit a shear wave, or that the core of the earth is a solid of very low rigidity. The idea suggested itself that a solid solution might satisfy this picture of a solid of low rigidity.

To test this, a solid solution of hydrogen in palladium was experimented with. The first question proposed was, "Does the occluded hydrogen affect the rigidity of the palladium?" The purpose of this communication is to state that apparently it does. The rigidity was measured by means of a torsion

pendulum. A small magnetized needle was suspended by a palladium wire half a millimeter in diameter. The needle was placed in an oscillating magnetic field of variable frequency. The period of the pendulum was obtained by measuring the frequency of the oscillator at resonance, which was found to be quite sharp. In the formula $\mu = 8\pi l/r^2 T^2$, l , r and T were determined before and after occlusion, which was produced by electrolysis. The results were quite erratic, some of the causes of which will be gone into later. However, there was a noticeable change produced in the rigidity of the metal, namely a decrease of rigidity with increasing occlusion. Some twenty different wires were tried and the change in rigidity measured when the wire was saturated with hydrogen. At first fairly long lengths of wire were used, but eventually it was found convenient to use short suspensions about 2.5 cm. long.

The average decrease in rigidity on saturation was found to be 13.7 per cent. The experiments were carried out *in vacuo*, in hydrogen and in air, but beyond a slight change in amplitude of the pendulum, no measurable change in period was noticed in the three cases. The best absolute value of the coefficient of rigidity of palladium into which no excess hydrogen has been forced was found to be $4.257 \pm 0.030 \times 10^{11}$. All palladium normally contains a certain amount of hydrogen apparently, and if this be driven off by passing a current through the wire, the above figure for the rigidity will be at least 12 per cent higher.

Starting with a piece of uncharged wire, a current of 10 amp. was passed through for a few seconds, heating the wire to redness. The rigidity increased 1.7 per cent. The current was again passed through for about a minute and the rigidity increased a further 8.4 per cent. The wire was then charged with about 400 times its volume of hydrogen. The rigidity decreased 16.6 per cent. Current was again passed through to drive out the hydrogen, this time for several minutes. The rigidity increased 22.8 per cent. The wire was again charged with about 450 times its volume of hydrogen and the rigidity decreased 21.0 per cent. It seems fairly certain, therefore, that the occluded hydrogen causes a decrease in the rigidity of the metal. The investigation is being continued further at Fordham and New York Universities jointly.

Note added in proof: The work of K. R. Koch in this field has not been overlooked, but will be discussed later.

Kinetics of Catalysed Polymerization of Styrene

INVESTIGATIONS of polymerization kinetics have often required rather cumbersome experimental methods, but Hammick and Langrish¹ have recently applied a convenient bromination method for estimating cyclopentadiene and indene to a study of the polymerization rates of these compounds in carbon tetrachloride. We have been using, for some time, a very similar method to follow the kinetics of the polymerization of styrene, catalysed by anhydrous stannic chloride, in carbon tetrachloride and chloroform solutions at 25° C. The amount of residual monomeric styrene in the reaction mixture is determined, at known intervals of time, by quantitative bromine addition to the double bond, using an excess of bromine which is estimated by titration in the usual way. The accuracy of the analysis (better

than 0.5 per cent) is not impaired by the presence of polystyrene; but with polystyrene in the presence of stannic chloride, the excess bromine must be destroyed without delay, in order to avoid a slow attack of bromine on the polymer. The styrene disappearing during polymerization has been proved to be equivalent to the polymer formed by weighing the amount of polystyrene precipitated in methyl alcohol¹. The polymers produced have molecular weights of the order 5,000 as determined by viscosity measurements.

With specially purified materials, the half-conversion period for polymerization may be of the order of one hour; but complex inhibition phenomena can appear if traces of impurity are present. In one series of experiments, with styrene concentrations up to 1.73 *M.*/litre in carbon tetrachloride, and with commercial 'c.p.' stannic chloride at concentrations 0.01–0.2 *M.*, polymerization was preceded by a period of total inhibition (varying from 0.6 to 4.2 hours with decreasing concentration of catalyst), after which polymerization would proceed to completion with a half-conversion period of one to eight hours. Experiments during the polymerization period have shown (a) that moisture produces a retardation inflection in the polymerization curve, (b) that dry hydrogen chloride is a temporary complete inhibitor, the polymerization resuming its course after an interval which may amount to an hour or more. In separate experiments, we have found that hydrogen chloride adds to the double bond of styrene at a measurable rate with a stannic chloride catalyst, and that addition proceeds considerably more rapidly in chloroform than in carbon tetrachloride. This behaviour corresponds with the observation that, in pure chloroform, polymerization was preceded by an inhibition period of 0.15 hr. with reactant concentrations which gave inhibition for 1.3 hr. in carbon tetrachloride. (In unpurified, commercial, 'practical' chloroform there was no initial inhibition.)

It seems probable that inhibition of polymerization by hydrogen chloride, introduced by intent or present as an impurity in commercial stannic chloride, is due to saturation by hydrogen chloride of the double bonds of those styrene molecules which have been activated by the catalyst, polymerization being prevented until the inhibitor has been removed by the addition reaction. If this explanation is correct, it follows, as the simplest interpretation (since hydrogen chloride is a complete polymerization inhibitor within the analytical error), that styrene and stannic chloride probably form a complex, capable of surviving several molecular collisions, which is responsible both for hydrogen chloride addition to styrene and for the chain-initiation step in the polymerization of styrene. Skraup and Freundlich² have provided evidence for the formation of complexes between stannic chloride and certain aromatic hydrocarbons having unsaturated side-chains; and this view of the polymerization catalysis is in accord with recent observations by Gee and Rideal³.

Detailed experiments are in progress.

Polarimetric Studies of Oxide Film Formation on Metals

THE polarimetric method¹ has now been applied to the study of the early growth of oxide films on copper and has given results in general agreement with those obtained by other workers using different methods². Typical curves showing the changes in Δ (the relative phase retardation of the perpendicular and parallel components of the incident plane vibration) during heating and cooling of copper mirrors in dry pure hydrogen and after replacement of the hydrogen by pure dry air, are given in Fig. 1.

Fig. 1.

A, ADMISSION OF AIR; T, TEMPERATURE RISE DUE TO INADEQUATE CONTROL

Calculations of the film thicknesses corresponding to the optical changes have also been made by means of approximate equations developed in the manner of Drude³, except that in the case of copper it was not found permissible to neglect some of the terms normally dropped. The thickness curves, together with those of Evans and Miley⁴ (dotted) are given in Fig. 2.

Fig. 2.

These latter would not be expected to be strictly comparable as they refer to oxidation of distorted surfaces beginning during polishing⁴, whilst the present results are for the re-oxidation of reduced annealed surfaces. It is also reasonable to expect differing degrees of activation or sintering and partial poisoning by sorbed hydrogen to have direct influence on the course of oxidation and to give rise to second order effects by modification of the optical constants of the base.

However, from this and other work mentioned, it is clear that the magnitude of the first rapid oxidation, even allowing for a considerably greater real surface, is much larger than would be expected from a sorption-diffusion oxidation theory⁶; and it seems that a controlling mechanism must be sought leading to differential equations of a similar form but involving other physical magnitudes. Detailed results and a discussion of them will be published in due course.

Hydrogen Bridges in Solid Pentaerythritol

Using the method of Fourier series, a quantitative crystal analysis of pentaerythritol, $C(CH_2OH)_4$, has now been carried out, and some of the interesting features of the determined structure will be given below.

Of the alternative space groups O_1-14 and S_4-14 chosen first by one of us¹, the latter should now be regarded as the correct one for this compound. The central carbon atom of a molecule is placed at 000 and surrounded tetrahedrally by the four methylenic carbon atoms at xyz , $x\bar{y}z$, $y\bar{x}z$ and $\bar{y}x\bar{z}$ with $x = 0.165$, $y = 0.140$ and $z = 0.10$, the interatomic distance for the C—C bond being hence 1.57 Å. The four hydroxyl oxygen atoms are also arranged in such general positions with the values of the parameters $x = 0.313$, $y = 0.265$ and $z = 0.00$. From these and above values the C—O bond distance is computed to be 1.46 Å. The oxygen atoms thus lie in the same plane $z = 0$ as the central carbon and besides not far from the base diagonals. If the hydrogen atoms of the OH groups are not taken into consideration, the molecule possesses approximately the symmetry of $D_{2d}-42m$, precisely S_4-4 , with one pair of primary alcohol radicals puckered upwards and the other downwards, namely,

all the bond angles of these atoms being approximately tetrahedral. Such a structure is found in the case of pentaerythritol tetrabromide vapour, in which, according to an electron diffraction study carried out by de Læzlo², the bromine atoms in the molecule form a square.

The most interesting aspect of the structure is the close approach of the hydroxyl groups on adjoining molecules. In the plane $z = 0$, four oxygen atoms, one out of each molecule, constitute a square of length of side 2.55 Å. This is shown by an idealized figure (Fig. 1), though strictly in the actual case the

line joining the central carbon and a hydroxyl oxygen in the molecule makes a small angle with one of the base diagonals.

Fig. 1.

The value 2.55 Å. for the above O—O distance, which must be bridged by a hydrogen atom, is considerably less than that assigned by Bernal and Megaw³ to their 'hydroxyl bond', while it is precisely the same as those found in the cases of KH_2PO_4 ⁴ and $NaHCO_3$ ⁵, in which, however, the O—O distance is not between two OH groups but between OH and O. At any rate it is evident that the molecules in a layer parallel to the (001) plane are linked more or less firmly to each other by hydrogen bridges in closed rings, where, according to Huggins⁶, the 'synchronized oscillations' may cause an increased stability of the intermolecular linkage. Such layer-like structure explains in a natural way the perfect cleavage along (001).

A detailed account of the present work will be published shortly.

Band Spectrum of Thallium Hydride

THALLIUM metal was heated in vacuum resistance furnace, which was filled with hydrogen at 500 mm. pressure. At a temperature of about 1,500° C., some bands in the yellow and red part of the spectrum were emitted. The same bands were also obtained in the emission from a thallium-copper arc burning in hydrogen at high pressure. At low pressure (less than 500 mm. mercury) in the arc no bands were present. With increasing pressure the bands get gradually stronger, and at a pressure of about four atmospheres the yellow and red bands are intense. Under the same conditions in the arc a fainter band system also appears in the blue and violet part of the spectrum.

The spectrum has now been photographed from 8000 Å. to 4000 Å. One of the strongest bands at

λ 5680 is shown in Fig. 1. The band is degraded to the red and consists of two branches, which are designated as *R*- and *P*-branches. Only the first two or three lines in each branch are sharp, and the lines then get gradually wider with increasing *K*-numbers. This widening of the lines, and the fact that no bands appear at low pressure in the arc, indicate that almost

Fig. 1.

every level of the upper state is predissociated. At low *K*-numbers, $0 < K < 9$, the *P*-lines are single. For $K > 9$ the lines are split up in two components with unequal intensity. As no *Q*-lines are present, the band probably is due to a $\Sigma - \Sigma$ -transition. In the thallium hydride molecule, both $^1\Sigma - ^1\Sigma$ and $^3\Sigma - ^3\Sigma$ are possible, but since the lines are diffuse (only the first eight or nine *R*-lines are resolved) it is

at present difficult to distinguish between these two alternatives.

A similar but much fainter band lies at λ 6150 Å. The two bands have a common upper state, and consequently they are designated as $0 - 0$ ($\nu_0 = 17,519.9 \text{ cm}^{-1}$) and $0 - 1$ ($\nu_0 = 16,174.5 \text{ cm}^{-1}$). The following constants have been calculated: upper state: $B_0 = 4.64$; $D_0 = -1.18 \times 10^{-4} \text{ cm}^{-1}$; lower state: $B_0 = 4.78$, $B_1 = 4.62$, $D_0 = -0.45 \times 10^{-4} \text{ cm}^{-1}$.

In the yellow and red part of the spectrum there are also some other bands with a somewhat more complicated structure, which show a characteristic widening of the lines similar to that of the two bands mentioned above. These bands can be followed into the far infra-red part of the spectrum.

Further details concerning the band spectrum of thallium hydride will be published later.

Points from Foregoing Letters

PHOTOMICROGRAPHS showing the effect of irradiation with neutrons upon the spleen and testicles of mice are submitted by Prof. M. Nakaidzumi, K. Murati and Y. Yamamura. A decrease in the number of lymph cells can be observed in the spleen, while in the testicles, cells in the various stages of spermatogenesis are more or less affected and destroyed.

By studying the precession of neutrons within magnetized iron, Drs. O. R. Frisch, H. von Halban, jun., and Jürgen Koch have found that the 'effective magnetic field' which accounts for the rate of precession is a considerable fraction of the magnetic induction *B*, at any rate much larger than the magnetic field strength *H*.

Drs. L. P. Kendal and L. H. Stickland describe experiments carried out with purified extracts of the glycolytic enzyme system; these may throw light on the earliest stages of the transformation of sugar-like substances, from which the muscle derives its energy. Unlike previous investigators, they find that co-enzymes (both magnesium ions and adenosine triphosphate) are needed for esterification.

Further experiments with substances related to vitamin B₁, which stimulate the growth of the mould *Phycomyces*, show, according to H. M. Sinclair, that pyrimidine plus thiazole give a large growth, and thiazole plus the amide of nicotinic acid give a fair growth (in a medium of glucose, asparagine and inorganic salts), but they are not active separately.

A number of substances separated from the unsaponifiable fraction of rice-germ oil (which has high anti-sterility, vitamin E, activity), together with some of their derivatives, are mentioned by Dr. A. R. Todd, Dr. T. Bergel, H. Waldmann and T. S. Work. Most of these compounds are biologically inactive. An aliphatic mono-unsaturated alcohol containing approximately 20 carbon atoms is considered by the authors of some significance, as a possible simpler derivative of the tocopherols (alcohols of approximate formula C₂₀H₃₈O₂) which have been shown to possess vitamin E activity.

Results of X-ray experiments with the fruit fly, *Drosophila*, leading to crossing-over of chromosomes

(producing mutation) are described by Prof. H. Friesen. Crossing-over in males was observed in the spermatogonial process both during normal nuclear division and also during the reduction division (meiosis). The frequency of spermatogonial crossing-over is not proportional to the X-ray dose.

Analysis of soils from Dartmoor, where sheep are liable to a type of anaemia (found to be due in New Zealand to a deficiency in cobalt), shows, according to J. B. E. Patterson, that the soil contains only 3.9 parts of cobalt per million on an average, whilst the soil in the lowland pastures, where the sheep are sent to recover, contains on an average 16.7 parts per million of cobalt.

It is stated by Father J. Lynch that when hydrogen is occluded in a metal, it apparently decreases the rigidity of the metal. In the case of palladium the decrease amounts to as much as 23 per cent.

Dr. G. Williams has used a bromination method for estimating styrene to follow the kinetics of its polymerization in carbon tetrachloride and chloroform at 25° C., with anhydrous stannic chloride as catalyst. Polymerization is rapid when specially purified materials are employed, but may be preceded by a period of temporary total inhibition with commercial stannic chloride as catalyst. Hydrogen chloride can act as a polymerization inhibitor, probably by addition to the styrene double bond.

Curves showing that the changes in the relative phase retardation of polarized light, falling upon copper mirrors, during heating and cooling in hydrogen and in air, are given by A. B. Winterbottom, also the film thickness of oxide corresponding thereto. The magnitude of the first rapid oxidation is much larger than expected from a sorption-diffusion oxidation theory.

A quantitative crystal analysis of pentaerythritol by I. Nitta and T. Watanabe has revealed an interesting layer-like structure. Molecules in a layer are linked more or less firmly to each other by the so-called hydrogen bridges, for which the O—O distance is found to be 2.55 Å. The molecular shape is similar to that of pentaerythritol tetrabromide in the vapour phase.

Research Items

Ancient Man in Devon

FOR some years past Mr. Reid Moir, in collaboration with Mr. and Mrs. MacAlpine Woods, has carried out archaeological investigations in the neighbourhood of Seaton and Beer in south-east Devon. These investigations have been confined to various deposits, ranging from Lower to, possibly, Upper Palaeolithic times, situated at some height above sea-level, but until recently no opportunity had appeared for examining the low-lying beds of the river valleys. Fortunately, however, a sewage plant is being erected on the Flood Plain at the junction of the River Coly with the Axe, and from the spoil heaps from the excavations a large number of flint artefacts have been found. The exposed sections are shallow and of small extent, but the succession of deposits, from below upwards, is clearly as follows: (1) Flood Plain gravel; (2) alluvium, with stones, 2 ft.; (3) alluvium, practically stoneless, 1 ft. 6 in. The surface of the Flood Plain gravel at the site examined is approximately 15 ft. O.D. Judging from what has been discovered in other parts of Great Britain, the stony alluvium resting upon the Flood Plain gravel would contain an assemblage of artefacts dating from Magdalenian—late Palaeolithic—times to the end of the Stone Age, and it is of interest to note that among the specimens recently found by Mr. Reid Moir and Mr. and Mrs. MacAlpine Woods are a number of blades of flint, including some definite and well-made burins. It is possible that these may be of Magdalenian date, and afford further evidence of the former presence of Palaeolithic man in Devon. Other specimens in the series appear to be referable to later epochs, though nothing which can with confidence be assigned to the Neolithic period has yet come to light. The examination of the Colyford site is being continued, and it is hoped that it and the artefacts discovered may be described in the near future.

Potassium and Paralysis

FAMILIAL periodic paralysis, as its name implies, is a hereditary disability characterized by periodic attacks of paralysis usually of the limbs. Aitken, Allott, Castleden and Walker (*Clin. Sci.*, 3, 59; 1937) have recently published observations which promise to illuminate this hitherto obscure malady. A patient was observed who attributed his paralytic attacks to heavy meals. It was found that the attacks could with regularity be produced about five hours after the ingestion of 250 gm. glucose, or by the injection of twenty units of insulin, or most surely by the combined effects of glucose and insulin. Analysis of the blood during and between the paralytic attacks showed that the onset of paralysis was associated with a fall of serum potassium from the normal value of 16–20 mgm. to below 12 mgm. per 100 c.c. serum. The paralysis could be relieved in 15 min. by the ingestion of 12 gm. potassium chloride. A fall in serum potassium occurs in normal individuals when glucose passes from the blood into the tissues, but in periodic paralysis the fall is unusually great, and it is this abnormality which constitutes the essential feature of the disease.

Structure of Protoplasm

DR. A. R. MOORE is probably giving expression to a view very widely spread among biologists when he argues (*Scientia*, 62, July 1, 1937) that the conception of protoplasm as an emulsion, suggested by Bütschli and supported by some of Hardy's experimental results, was quite inadequate even to account for the behaviour of the cytoplasm of the cell. A useful purpose is probably served, nevertheless, in passing in review some of the considerations which suggest a more 'structural' basis. Thus in some merogonic hybrid embryos of echinoderms the tempo of cleavage of the cells of the hybrid is clearly determined by the parentage of the cytoplasm—not of the nucleus. In sea-urchin eggs, as the result of centrifugal action, it may be possible to obtain cells, clear of all dense inclusions, which behave quite normally on fertilization, but this clear hyaloplasm, although without visible structure, almost certainly has a structural framework conserving its role in the transmission of hereditary characters. The phenomena of flow in protoplasm is shown to be consistent with the presence of fibrillar elements; in this way alone would it seem possible to explain the behaviour of plasmodia of Mycetozoa, which will flow through hard paper filters with average pore size of 1μ though they are destroyed when forced through sieve pores less than 0.20 mm. in diameter. Dr. Moore's conclusion, that protoplasm contains polar particles or chains of molecules which, when occasion requires, link themselves into structural features, not only agrees with modern views of the mechanism of wall deposition at the surface of the plant protoplast, but also reconciles very generally the contrast between the mobility of the cytoplasm and the necessity for a structural framework to account for its performance in cell division and heredity.

Researches on Indian Fishes

IN *Current Science*, 5, No. 7, 1937, there are two interesting articles on fishes. The first is entitled "Geographical Distribution of Indian Freshwater Fishes and its Bearing on the Probable Land Connections between India and the Adjacent Countries" by Sunder Lal Hora, assistant superintendent, Zoological Survey of India, Calcutta. It is a summary of the remarks made at the Hyderabad meeting of the Indian Science Congress, during a joint discussion between the Sections of Geology, Botany and Zoology, on Wegener's theory of continental drift with special reference to India and the adjacent countries. The evidence provided by the distribution of the freshwater fishes of India indicates an eastern origin of the fauna and its subsequent dispersal to the west. The close relationship between the Indian and the African freshwater fishes can only be explained on the assumption of a land connexion between the two countries. The absence of the Schilbeidae from Ceylon and their presence in Africa suggests that Ceylon may have become separated from India at a stage earlier than the severance of the land connexion between Africa and India. In the second paper, P. Sen, entomologist, Bengal Public Health Department, "On the Food Factors of the so-called Mosquito-

Destroying Fishes of Bengal—*Panchax panchax*, *Barbus stigma*, *Esomus danricus* and *Trichogaster fasciatus*", shows that the plankton flora and fauna form the main food of *Panchax* although they also eat insect larvae, that *Trichogaster* eats plankton with filamentous algae, and that *Barbus* and *Esomus* are also essentially vegetable feeders. Thus *Panchax* alone of the four eats insect larvae, and these only form a small portion of the food. There is apparently no justification in assuming that these fishes would eat the *Anopheles* larvae except in very small numbers.

Inheritance of Leukemia in Mice

LEUKEMIA is a tumorous condition in which the leucocytes of the blood multiply rapidly. The symptoms are very similar or identical in mouse and man. There is often enlargement of the spleen and lymphatics as well as an enormous increase of the number of leucocytes in the blood. Dr. E. C. MacDowell (*J. Hered.*, 28, No. 4) has described experiments on the inheritance of leukemia in mice which are of particular interest in their bearing on the relation between intrinsic and extrinsic factors. By brother-sister matings through eighteen generations, a genetically uniform leukemic strain of mice was obtained. In a total of more than 600 mice, however, 10 per cent always failed to develop leukemia. But the offspring of the negative mice developed the disease with the same frequency of 90 per cent. It is concluded that the 10 per cent negatives represent the balance between the genetic constitution of this particular strain and the particular environment in which they developed. When a negative strain is crossed with a male from the leukemic strain, the F_1 show an incidence of nearly 45 per cent, and when F_1 males are back-crossed to the neutral strain the incidence of leukemia is again halved. When the leukemic heredity is derived from the mothers, the incidence of leukemia in the offspring is significantly higher in all cases. By careful analysis and variation of the laboratory environment, it will probably be possible to determine which extrinsic factors are effective. It is also significant that the role of extrinsic factors varies with the intrinsic factors present.

Research on Wood-destroying Insects

THE *Journal of the Royal Society of Arts* (85, 407; 1937) contains a report of a lecture given by Dr. R. C. Fisher of the Forests Products Research Laboratory on the above subject. Special reference is made to the death watch beetle (*Xestobium rufovillosum*), and it is pointed out that there appears to be a definite relation between the presence of fungal decay in timber and the occurrence of this insect. It was also shown that the temperature and moisture content of timber are important factors in determining the rate of development of the beetle. Warm, dry conditions and the absence of fungal decay are unfavourable for this insect. Damage is usually most severe at, and often confined to, the built-in ends of timbers in buildings where ventilation is poor and where conditions are favourable for the accumulation of moisture and consequent risk of decay. The outstanding conclusion of recent biological studies is the importance of the presence of fungal decay. Experiments are in progress to determine exactly how fungal decay renders timber suitable for infestation. Also the fact that *Xestobium*

can continue to live and develop very slowly in decay-free timber has to be taken into consideration. Reference is made to frequent reports in the press, and by authorities seeking funds for repairs, of damage caused by the beetle to churches and other buildings. The result has been a general impression that the creature has increased its activity during the last few years. This idea, however, is erroneous, and the apparent spread of the beetle can be best explained by the increased interest taken in its occurrence, which leads to more thorough inspection of old timbers in buildings.

Cytology of the Genus *Poa*

J. M. ARMSTRONG has examined the chromosome numbers of twenty species of the grass *Poa*, with the result that previous suggestions are confirmed and extended: (1) that polyploidy is associated with species formation; diploid to dodecaploid species are described, the basic chromosome number being seven; (2) that aneuploid species are also present; three aneuploid species have chromosome numbers suggestive of a $9n$ origin (*Canadian J. Res.*, 15, June 1937). An interesting examination is made of the possibilities of the maintenance of a certain aneuploid strain with 54 chromosomes. In view of the obvious difficulties in the way of maintaining constant such an aneuploid strain through normal sexual fertilization, an apogamous origin of embryos from sporophytic tissue in the ovule seemed likely and has frequently been suggested. Armstrong, however, shows that the fertility of the pollen mother cells is surprisingly high and that polyembryony frequently occurs, but that the embryo sacs may all arise from megaspores produced after the normal reduction division. The author points out that the univalent chromosomes appear regularly to be included in the nuclei after reduction division. Four univalents are concerned, and in view of the high chromosome number their presence may not disturb the genetic balance if they undergo random segregation. Such random segregation would give 6 out of 16 pollen grains with 2 univalent chromosomes and, in view of the frequent occurrence of polyembryony, with good opportunities of meeting female nuclei with 2 univalent chromosomes also. Such gametes would contain 27 chromosomes in all and their union might maintain the strain by ordinary sexual reproduction; the author concludes that this is the method in which the aneuploid 'Mammoth' strain of *Poa pratensis* is reproduced.

Fulgurites from Witsands, Kalahari

AMONG the sand-dunes on the south-east border of the Kalahari desert, A. D. Lewis (*S. Afr. Geog. J.*, 19, 50; 1936) estimates that there are not fewer than 2,000 fulgurites ('lightning tubes') over an area of eight square miles. Curiously, however, the natives say that storms are not frequent and they have never seen the dunes struck by lightning. The friable tubes of fused silica are mostly found as broken fragments lying in the hollows between the dunes, and only rarely are they seen *in situ* projecting a few inches above the surface of the sand. Five tubes extending vertically downwards were excavated, but without reaching the lower end. The longest recovered (as fragments) measured 8 feet and showed some branching with a variable form and diameter (0.2–0.5 in.) along its course. Larger tubes (up to 2 in.)

have collapsed with the formation of longitudinal ribs. In one case threads of fused silica extend across the cavity, suggesting that the tube again expanded while still in a plastic condition. The sand surrounding the longest tube was seen to be "darkened as if burnt". Some previous records mention that the loose sand adjacent to the fulgurite is iron stained, suggesting that iron was vaporized from the fused silica. The author accepts, though apparently somewhat reluctantly, the view that these tubes were formed by lightning. One of his alternative suggestions is that they were formed by meteorites; this being supported by the statement that lechatelierite (silica-glass) has been found in meteorites—a statement that is quite incorrect.

The Baffin's Bay Earthquake of 1933

LATE on November 20, 1933, a strong earthquake was recorded at stations all over the world. The early estimates made at Kew, Strasbourg and elsewhere showed that the epicentre lay in Baffin's Bay, and, about a week later, it was reported that the shock was felt in western Greenland. The earthquake is one of much interest, for we have no record of any other in this part of the world, and the epicentre was so situated that the numerous stations in Europe, North America and Japan all lay within moderate distances from it. In response to circulars issued by Dr. A. W. Lee of the Kew Observatory, 99 records were placed at his disposal, more than two thirds of them from stations lying between 25° and 40° from the origin, and these are studied by him in a recent valuable memoir (*Meteorol. Office, Geophys. Mem.*, No. 74; 1937). The closest representation of the travel of the P waves to distances of 25° – 50° is, he finds, given by a table based on one prepared by Gutenberg and Richter, the resulting position of the epicentre being lat. 73.3° N., long. 70.2° W., and the time at the origin 23h. 21m. 31.5s., G.M.T. The surface waves were very large, showing that the focal depth was not considerable. Indeed, from the average length (about 4 sec.) of the interval between the arrivals of the P and sP waves, it follows that the depth was about 10 km. below the surface. The apparent velocity of the P waves was uniform for epicentral distances from 25° to 40° and again from 45° to 50° , the velocity changing by 17 per cent from 40° to 45° . There are discrepancies between the observations of S and the existing tables. A new table for S for distances 25° – 50° was, however, computed from the travel-times for P on the assumption that Poisson's ratio is constant for the rocks traversed by the waves, and the agreement between the observations and this table is satisfactory.

The Tenham Meteoric Shower of 1879

IN 1935, a collection of 102 complete meteoric stones, of aggregate weight about 108 lb., was presented to the British Museum by the widow of Mr. Benjamin Dunstan, formerly Government geologist of Queensland, who had been collecting information of the history and composition of the meteorites. This collection, described by Dr. L. J. Spencer in No. 156 of the *Mineralogical Magazine*, represents a remarkable shower that fell in 1879 at Tenham in a remote district of south-west Queensland. Thirty years ago, two large stones and one small stone (total weight, 134 lb.) from this district were acquired for the British Museum. Dr. Spencer relates the

history of these three "Warbreccan stones", which are almost certainly three belonging to the original collection made by Mr. M. Hammond, an eye-witness of the fall and who was alive in 1936. A chemical analysis of specimen stones made in the Government Chemical Laboratory at Brisbane in 1913 shows that their composition is that characteristic of the stony variety, that is, masses of crystalline rock with a small metallic content, as distinct from the type composed largely of metallic iron. This collection from the Tenham shower is stated to be the most complete example of a meteoritic shower in the British Museum collection of meteorites. Dr. Spencer describes schematically the passage of a stony meteorite through the earth's atmosphere, its stage of incandescence commencing at a height of about 100 miles; the subsequent explosion of the meteorite due to intense surface heating and to air pressure, followed perhaps by a second explosion and the fall to earth of the resulting shower of stones, the velocity of which is checked generally to that of an ordinary falling body—about 70 metres a second. In the case of a large mass of metallic iron, it will survive disintegration more easily and may arrive at the earth's surface with much greater velocity.

The Cannizzaro Reaction

THE mechanism of the Cannizzaro reaction, in which an aldehyde, for example, benzaldehyde, reacts with water in the presence of an alkali to give an acid and an alcohol ($2R.CHO + H_2O = R.COOH + R.CH_2OH$) has been investigated by using alkali dissolved in deuterium oxide, D_2O (Bonhoeffer and Fredenhagen, *Naturwiss.*, 25, 459; 1937). No deuterium was found in the CH_2 group of the alcohol. This means that the hydrogen from one aldehyde group is transferred directly to the carbon atom of the other aldehyde molecule (possibly after the two molecules have combined to give an acetal compound), without a dehydration of a hydrated aldehyde molecule and transference of molecular hydrogen.

Tests for Random Observations

W. O. KERMAK and A. G. McKendrick (*Proc. Roy. Soc. Edinburgh*, 57, 223; 1937), starting from an investigation of the fluctuation in the death-rate from ectomelia in mice in an experimental epidemic, have arrived at simple tests which will help to decide whether a series of numbers is random, that is, due to mere chance, or evidence of a real cause. A series which conforms to these tests is not necessarily random, but is likely to be so. On the other hand, failure to conform is evidence of non-randomness. The calculation depends on the runs and gaps, the average lengths and standard deviations of which are compared with what would be expected from pure chance. One obvious limitation of the tests is that they make use only of qualitative relationships and do not take into account exact magnitudes, so they do not make full use of the information available. On the other hand, there is the compensating advantage that no assumption is made about the law of distribution of the observations. These tests are applied to some examples, including Tippett's random numbers, telephone numbers, duration of measles epidemics, Swedish death-rates, Edinburgh rainfall and Edinburgh temperature. The results work out as might be expected in most cases, but the Edinburgh climate seems to defy prediction.

The First International Acoustical Conference

THERE is scarcely any subject which, during the last few years, has assumed greater commercial and social significance than acoustics. Alongside has come the steady growth of noise—that is, unwanted sound—which in its many aspects is beginning to stir the consciousness of the public to such an extent that it is demanding measures for relief in the more outstanding cases. Acoustics has furthermore developed a large specialized terminology, and the need for agreed measuring units and standards has become more and more pressing.

In Great Britain such questions have been dealt with by a British National Committee under the auspices of the British Standards Institution. Under the chairmanship of Dr. G. W. O. Kaye, this Committee has developed and classified an extensive glossary of acoustical terms*, particular attention being given to units and standards, among them the scales and units of loudness and energy-level. As regards these latter, which are of especial importance, considerable divergencies have unfortunately prevailed in the practices of different countries, not only as regards the scales, units and zeros of the standard reference tones, but also in the listening techniques and phraseology employed. In its work, the British Committee kept in mind the desirability of eventual international agreement in such matters and to this end set up specifications dealing with the standard reference sound (a sinusoidal plane progressive wave of a frequency of 1000 cycles per second), and the arbitrary zero of reference (0.0002 dyne per sq. cm.). The "phon" (a name we owe to Barkhausen) was adopted as the unit in the subjective scale of equivalent loudness, while the use of the "decibel" (a name which originated in America) was restricted to the scale of the associated energy or pressure level.

In July of this year, the first international conference on acoustics was summoned in Paris under the auspices of the International Electrotechnical Commission (I.E.C.), some sixty delegates from

thirteen countries assembling under the presidency of M. Duval, president of the French Electrotechnical Committee. Substantial agreement was reached in the several sections set up to deal with vocabulary, fundamental units and methods of measurement, electro-acoustics, and noise abatement. Chief interest centred in the questions of fundamental units and methods of measurement, and it is satisfactory to learn that the proposals eventually adopted are in complete agreement with the specifications submitted by the British delegation under the chairmanship of Dr. Kaye. The "phon" and the "decibel" are accordingly accepted as international units, so that an important contribution to international acoustical measurements has been achieved. Particular mention should be made of the helpful and conciliatory outlook of the United States and German delegations, of whom Dr. Harvey Fletcher and Dr. Gratzmacher were the respective chairmen.

An inquiry into the present position of objective noise meters indicated that while great progress had been made, there was not enough experience available to approve at the present juncture the specification and standardization of a 'universal' noise meter which will measure on the phon scale any and every type of sound. Other points dealt with included the standardization of methods of testing microphones and loud-speakers, the different procedures adopted in various countries for measuring acoustic absorption coefficients by the reverberation method, the methods used to investigate the transmission of air-borne and impact sounds in buildings, and the steps taken in different countries for reducing noise.

The pronounced success of the Conference owed much to the valuable preparatory work of the I.E.C. and the co-operation of M. Valensi, secretary of the Comité Consultatif International Téléphonique. It was agreed at the final plenary meeting that the work of future conferences should be administered by the Federation of National Standardising Bodies known as the International Standards Association, the I.E.C. concurring and actively collaborating.

Concentration of Solutes in Vacuolar and Cytoplasmic Saps

By Dr. E. Phillis and Dr. T. G. Mason, F.R.S.

IF 25–30 gm. of mature leaves of the cotton plant are rolled up, wrapped in cloth, the wad placed between two disks about 2 in. in diameter and the whole put in the jaws of a small vice, sap is expressed on the application of pressure. As the sap flows out of the wad, much of the leaf is squeezed out from between the disks. To obtain more sap, the tissue must be collected into a ball and again wrapped up in the cloth. On the application of pressure, sap is again expressed. This process can be repeated three or four times; but a point is reached when even

under the greatest pressures that can be obtained in the vice, the yield of sap amounts to only a few drops. If now the residue from which sap has been expressed is frozen at -16°C . and then thawed, much more sap can be obtained on the application of very small pressures.

It was observed by Dixon and Atkins¹ that the concentration of solutes increased in successive fractions. They also discovered that preliminary treatment of the leaf by freezing or by exposure to anaesthetics greatly increased the concentration of

solutes over that in sap expressed from untreated tissue. Typical results from our own experiments for calcium, magnesium and potassium are shown in Table 1.

TABLE 1. SAP EXPRESSED IN VICE.

		No. of fractions			Frozen residue
		1	2	3	
ml. sap from 100 gm. fresh wt.		11.2	11.4	12.7	23.6
Concentration (mgm. per 100 gm. water)	Calcium	490	535	568	848
	Magnesium	54.4	57.3	61.2	99.7
	Potassium	201	218	238	264

It will be seen that much sap was released and that there was a marked increase in the concentration of solutes as a result of freezing the residue. The usual explanation (Walter*) for the increase in concentration in successive fractions is that pressure has two effects, one being the expression of water through the cytoplasm and its membranes, solutes being retained in the vacuole, and the other the bursting of cells and consequent liberation of vacuolar solution. The change in concentration in successive fractions is assumed, therefore, to be due to filtration of water and concentration of the vacuolar solution. The increased concentration resulting from freezing is generally interpreted as due to the breakdown of impermeable membranes and the release of the vacuolar sap. It is very commonly assumed by botanists (Searth and Levitt*) that the cytoplasm in mature leaves contributes but little sap and that the bulk of the sap expressed even from previously frozen tissue comes from the vacuole. Perhaps it is also true that many botanists still believe that the continuous phase of cytoplasm is water (cf. Stiles*), and that some of this water may be expressed, particularly after coagulation of the cytoplasm which is assumed to occur as a result of freezing.

Somewhat to our surprise, we have observed that if leaves are carefully placed one on top of another between the relatively large plates of a hydraulic press, the concentration of sap in successive fractions does not necessarily increase as the pressure is increased. The concentrations are also found to be lower than when leaves are pressed in the usual way in the vice. In the hydraulic press, using carefully arranged leaves, they are not squeezed out from between the plates, and the shearing forces that arise in the vice, as leaves are redistributed in the wad as its shape is changed, are negligible or absent. The presence or absence of shearing forces appears to be crucial. The results for a duplicate sample of leaves to that used in Table 1 are shown in Table 2.

TABLE 2. SAP EXPRESSED BY HYDRAULIC PRESS.

		No. of fractions			Frozen residue
		1	2	3	
Pressure (lb. per sq. in.)		6,000	10,000	16,000	16,000
ml. sap from 100 gm. fresh wt.		13.1	13.5	11.6	23.5
Concentration (mgm. per 100 gm. water)	Calcium	420	414	424	886
	Magnesium	46.9	44.5	46.5	107.2
	Potassium	163	181	176	253

It will be seen that there is again a great increase in concentration when the residue is frozen and pressure applied. Of outstanding importance is the fact that the concentration remains nearly constant and does not rise as the pressure is increased. There is thus no support for the view that water is filtered under pressure through the cytoplasm. Other causes for the increase in concentration in the vice must therefore be sought. It will be noticed that even the first fractions in the vice exceeded those in the hydraulic press. If the results are graphed, it will be seen that the curves for the two methods of expressing sap diverge from a common origin. It is noteworthy that even under pressures so high as 16,000 lb. per sq. inch, only approximately half the sap was expressed.

The meagre proportion of the total sap present in the leaf that can be expressed by these high pressures does not indicate that the continuous phase of cytoplasm can be water, as is generally assumed, for as much water can be expressed from a gelatin gel under a pressure of 2,000 lb. per sq. inch as is liberated* by freezing at -20°C . It must be borne in mind that nearly half the volume of the mesophyll cells in cotton, excluding the cells' walls, consists of cytoplasm. This is contrary to what is usually believed to be the case (cf. Stiles*); but Iljin's* measurements show that cotton is by no means exceptional in this respect. It would seem that the continuous phase of active cytoplasm, as Lepeschkin* suggests, is a liquid, composed probably of proteins, lipoids and water. This liquid, as we have previously* suggested, would appear to have solubilities and diffusion constants quite different from those of water, and to be dependent for its origin and maintenance on respiratory energy. With such a concept of the composition of the continuous phase of cytoplasm, the results already described would be explained as follows.

When the leaf is pressed in the hydraulic press, the vacuolar sap escapes through fissures in the cytoplasm. The continuous phase of the cytoplasm, for which Lepeschkin has proposed the term 'vitaid', is not decomposed by this direct pressure into its component parts. In the vice, on the other hand, shearing forces are operating. We thus assume that the 'vitaid' molecule is decomposed by comparatively small shearing forces though able to withstand direct pressures of considerable magnitude. Thus in the vice a gradual decomposition of the 'vitaid' molecule occurs. It is broken up into proteins, lipoids and water, while the solutes which were in solution in it are now dissolved in the water and escape with the vacuolar sap, which in the leaf of the cotton plant is considerably more dilute than the sap that is produced as a result of the decomposition of the 'vitaid' liquid. The great increase in concentration and the large amount of sap produced when the residue from the hydraulic press is frozen is due to the decomposition of the 'vitaid' liquid by the shearing forces that arise as a result of the formation, and perhaps the disappearance, of ice in the vacuole and the intercellular spaces.

Some confirmation of this hypothesis is furnished by the following experiment, the results of which are shown in Table 3. If the residue from the hydraulic press from which all the sap available at a pressure of 14,000 lb. per sq. inch has already been expressed, is divided into two portions, one of which is frozen and one of which is gently rubbed between the fingers and thumb, it will then be found that further

sap can be expressed from each portion merely by squeezing in the hand. The volume obtained after rubbing, as might be expected, is slightly less than that after freezing, for the shearing is less thorough. The concentrations in the two residue saps were approximately equal in this experiment, although in other experiments, those in the finger-rubbed fractions have been slightly below those in the frozen fractions. The maximum pressures used give no indication of the ease of expression of sap. From the fresh tissue, no sap was obtained below a dial reading of 4,000 lb. per sq. inch hydraulic pressure, while with both the residues, most of the sap was expressed before the needle left the zero mark.

TABLE 3. EFFECT OF PREVIOUS TREATMENT OF RESIDUE ON SAP OBTAINABLE UNDER PRESSURE.

	Fresh leaves	Treatment of residue	
		Finger-rubbed	Frozen
Maximum pressure (lb. per sq. inch)	14,000	14,000	14,000
gm. sap from 100. gm. fresh weight	24.4	30.0	36.7

		Fresh (hydraulic pressing)	Residue treatment	
			Finger-rubbed	Frozen
Concentration (mgm. per 100 gm. water)	Calcium	256	718	712
	Magnesium	44.0	104.7	106.8
	Potassium	275	599	604

It is interesting to note that Audus⁶ has found that rubbing a leaf on both sides with a finger stall or merely bending the leaf increases respiration 2-3 fold.

If we are correct in the interpretation of the results, we can form approximate estimates of the

concentrations of solutes in the vacuole and cytoplasm respectively. The vacuolar estimate is obtained from the lowest concentration obtainable by direct pressing. This may be an over-estimate, for slight shearing forces will cause some cytoplasmic decomposition; for example, when brittle leaves are pressed in the hydraulic press, successive fractions of sap show diminishing concentration, due, we believe, to shearing forces developed in the leaf mass during the initial stages of compression. The action of such shearing forces is associated with the presence of chloroplasts in the expressed sap. If the vacuolar sap could be completely expressed the residue should, on decomposition, yield a sap representative of the cytoplasm, but incomplete vacuolar pressing will cause dilution of the cytoplasmic sap and an under-estimate of its concentration. In the leaves used in the experiment just described, the concentration in the cytoplasm must have been more than double that in the vacuole.

Methods used for the extraction of sap invariably include some process which we believe leads to destruction of the 'vitoid'. These processes include boiling⁷, freezing, grinding¹⁸ and treatment with anaesthetics¹⁴. All saps obtained by these processes are, therefore, mixtures of vacuolar sap with that produced on decomposition of the vitoid. It will be necessary in the future, we think, to distinguish between the true (vacuolar) sap and that derived from the destruction of the cytoplasm.

International Congress for Short Waves in Physics, Biology and Medicine, Vienna*

PROF. H. THIRRING, in an address made during the opening ceremony of the Short Wave Congress held in Vienna on July 12-17, referred to the many fields of application of Hertzian waves in research, medicine and radio technology. These fields are to some extent interdependent, and there are in particular medical and biophysical problems which require the collaboration of biologists, physicists and radio-engineers if they are to be solved satisfactorily. Thirring pointed specially to the urgent problem of dosage measurement in short wave therapy and to the fundamental scientific question of the mode of biological action of short waves: specific or thermal. These problems occupied a prominent position in the Congress, and, together with purely physical papers, will form the substance of the

present report; the review articles in the various sections and the fifty or so papers in the medical section will not be dealt with. (Number in brackets in each heading indicates the number of papers presented.)

(1) *Production of ultra-short waves* (11). Most of the papers dealt with retarding field or magnetron circuits devised for production of the shortest waves; the most interesting perhaps was the 14 cm. wave retarding field generator with resonant cavity as frequency stabilizer, demonstrated by Dallenbach, Alderding and Kleinstaub. The demonstration showed the remarkable frequency stability attained and the modulation of the 14 cm. wave. Another retarding field system was described by Meng and Potapenko, who have constructed exceedingly symmetrical micro-tubes for high-order oscillations of wave-length ~ 1 cm. McArthur described a new

* Internationaler Kongress für Kurzwellen in Physik, Biologie und Medizin. Referate und Mitteilungen. (Wien: Brüder Hollinek, 1937).

magnetron, of single (water-cooled) anode type with permanent magnet and concentric tube transmission line, giving 10 watts at λ 4.8 cm. Grookowsky and Ryzko discussed the increased efficiency obtainable with 4-anode magnetron tubes when the usual tungsten cathode is replaced by oxide-coated nickel. The Okabe electron beam magnetron was described by Joji Ito.

(2) *Transmission: Ionosphere research* (12). Van der Pol sketched a theory of propagation of ultra-short waves over the earth, starting from the Maxwell equations, with proper boundary conditions; he showed that 7 m. waves must diffract considerably beyond the horizon, with a strong attenuation which is due to absorption by the ground. Southworth discussed transmission in pipes or cylindrical rods of dielectric. For a hollow metal pipe the diameter must be at least 0.58λ . The resonant cavity is a special case of this system, and may be used as a frequency determining unit or as an impedance matching device, and perhaps as a new means of 'irradiating' laboratory specimens.

Six of these papers dealt with the ionosphere, beginning with a review by Zenneck. Burkard discussed the information concerning the ionosphere and its diurnal and seasonal variations obtained from a statistical treatment of amateur radio reports—as many as 10,000 per month. Reports for the summers 1934 and 1935 (sunspot minimum—single reflection, presumably from F_1) gave 240 km. as the mean height of the layer. Ito Yoji described ionosphere studies during the total eclipse of June 19, 1936, when there was found 47 per cent decrease in electron density in F_1 , but practically no effect on F_2 . Fuchs described a method of determining the absolute temperature in the ionosphere, obtaining the values $F_1 > 400^\circ$, $F_2 > 1,400^\circ$ K., so that the daily division into the two layers is presumably due to gas-thermal effects. Hals described the discovery of the Hals-Störmer echoes, and Fuchs provided an interpretation, as an ultra-violet ionization phenomenon of the upper atmosphere.

(3) *Absorption and dispersion in chemical systems* (4). Potapenko described a new modification of the Drude-Coolidge method for determination of ϵ' and ϵ'' ; together with Keutner, he has used the method for measurement on monohydric alcohols and glycerol, finding, as others have found, approximate agreement with the Debye theory. Williams has measured the absorption of 1.25 cm. waves by ammonia gas, the ray being diffracted from an échellette grating after passage through the gas, and the intensity being determined with a crystal detector.

(4) *Dielectric properties of tissues: heat production in tissue and tissue models* (4). The papers on this subject brought out clearly the large number of factors which must be taken into account in considering the possibility of selective heating of tissues by ultra-short waves. Given fixed values of ϵ (dielectric constant) and κ (specific conductivity) for the various parts of a body, the matter is relatively simple; if, however, both ϵ and κ are strongly dependent on frequency and on temperature, the calculation of the optimal wave-length for selective heating of a certain tissue becomes impossible without complete experimental dispersion curves for all the tissues concerned. In regard to κ , Schaefer and Rajewsky have now extended their measurements on blood to several other tissues, while an admirable series of measurements by K. Oswald shows the dependance of both ϵ and κ on frequency even in the

ultra high-frequency region. A further complicating factor may be the very large effect of field intensity on dipole losses in solutions of *zwitterions*, observed by Schmalzer in the case of tetra-*n*-butylammonium bromide in benzene, although it is not yet known what proportion of the observed high-frequency conductivity of tissues is due to substances of this type.

This complexity in the physical properties of heterogeneous systems makes it important to obtain empirical information concerning selective heating by experiments with 'models', however approximate such information may be. Pätzold described measurements of the relative heating of juxtaposed layers of fat and muscle in the condenser field at λ 6 m. and 1 m., the results of which are in substantial agreement with those calculated from Oswald's data. He has also measured the relative heating of layers of salt solutions in a solenoidal field as a function of position, wave-length and number of coil windings, and further considered the possibility of applying ultra high-frequency energy by 'irradiation', on the basis of *Halbwertschicht* determinations on salt solutions and tissues at λ 4.3 m.

(5) *Physics and chemistry of possible specific (non-thermal) effects* (17). It soon became clear that 'non-thermal' effects might be placed in several categories: (a) Specific electrical and mechanical effects, the existence of which, in principle, can scarcely be doubted, resulting in chain configuration of suspended particles, in decreased degree of dispersion, change in viscosity, etc., dependent on field strength and type of field but not on frequency. These effects were admirably discussed by Krausz-Ergen. (b) Possible specific chemical and biochemical effects, the existence of which has not yet been satisfactorily demonstrated, although frequently asserted. These were discussed by Königer, who suggested possible 'resonance' absorption effects, in the sense of Romanoff's theory. Bateman and Rosenberg discussed the physical conditions which have to be satisfied for the experimental elimination of thermal effects. (c) Possible non-thermal physiological effects on cell suspensions, when thermal effects can be avoided by use of proper experimental conditions. According to Hasché, Leung and Loch, the field has no effect on *B. coli* and *Staph. pyococcus aureus* under most conditions of wave-length, intensity and type of suspension medium, although a few inconsistent observations have been made at λ 3.5 m.; similar negative results were obtained by Ruete with *B. coli* and several moulds, and by Malov, with *Drosophila* (mutation rate and lethal action). The observations of Roth (development of exposed seeds), of Wertheim ('biopositive' effects on yeast) and of Schweinburg (on rabies virus), with their less satisfactory control of heating, do not necessarily contradict these negative results. (d) Effects on large bodies: 'specific' effects opposite to 'heating' effects. Most of the observed physiological effects belong in this category; they could be the result of (a) or (b), or else—more probably—merely thermal effects of a special kind, due to the peculiar distribution of temperature gradients in the body which results from exposure to the field. None of the many experiments of this type described at the Congress contributed essentially to the solution of the problem.

(6) *Measurement of absorbed energy in ultra-short wave therapy* (9). The difficulties of a satisfactory measurement of 'intensity' (watts absorbed/sec.) were enumerated by several contributors, and a number

of modifications of known procedures were described. In particular, Mittelmann has used a method involving the preliminary determination of the effective resistance of the circuit with a secondary transmitter and valve voltmeter, followed by measurement of I or E during treatment with thermo-cross and dynamometer. Riesinger measures the total anode dissipation of his transmitter with ammeter and voltmeter, and the heat dissipation with a photo-cell and a reflecting bimetal strip fixed to the anode, the difference representing the high-frequency energy

generated. It seems, however, uncertain whether this arrangement can be used, as Riesinger claims, as a dose intensity indicator. Schwarz suggested two rapid methods: first, determination of 'spread' of the resonance curve by means of variable condenser and Braun tube; secondly, measurement of true field across the object by small electrometer electrodes mounted in the condenser plates. The papers on the subject gave the impression, however, that the problem is still far from being solved.

J. B. BATEMAN.

The Science of Archives in South Africa*

STUDY and work connected with archives have been recognized as a science, and a scientific system of keeping archives has been evolved; while not only is a high standard of attainment and a wide range of knowledge of scientific method and results demanded of the archivist, but also in certain European countries provision has been made for his technical training.

Archives constitute a fundamental source of historical information, and hence the introduction of the moving picture—the cinematograph film and the 'talkies' have, in the problem of their conservation, forced on the attention of the archivist a number of practical questions, the method of dealing with which has yet to be determined on scientific lines.

In South Africa, prior to the date of the Union, the Cape Province gave attention to this subject more than half a century ago, and the Transvaal since about 1902. In 1919 the Union Government took the first serious step in co-ordinating the archives of the four provinces.

The administration of Union and Provincial Archives was centralized in a chief archivist, and by legislation of 1922 Union and Provincial archive depots were created, the former at the seat of government of the Union, and the latter at the seat of the Provincial administration. The centres thus are in Cape Town, Pretoria, Pietermaritzburg and Bloemfontein, each in charge of an archivist, and the whole administration centralized in the chief archivist. This system secures uniformity of administration, arrangement, classification, inventorying, methods of preservation and general care. It has resulted in straightforward administrative efficiency, and experience has taught that it is the only satisfactory method. Experts in archive economy the world over endorse this system.

The Archives Department is a young branch of the Public Service of the Union of South Africa. Its advance, unspectacular but steady, during the last decade or so, was marked by a persistent claim to recognition as an integral part of the Government machinery and the necessity for its personnel to be men with a certain standard of education and an aptitude for the work.

An archives depot is not static, and must increase in quantity and quality as the years pass. The

Department was conceived, no doubt, as a branch of the service with great possibilities. Its growth was slow at first, and to some extent stunted because it had to overcome many prejudices. When it was given a place in the Government machinery, it had to live down the prevalent conception that it was a warehouse for the storage of records with someone in charge to keep them from deterioration and permit their consultation when necessary. It had to have a proper home and the right kind of vitamins in its food to allow it to develop. But this stripling of a department struggled on, facing all the obstacles which beset it.

South Africa had the advantage of studying the systems of similar institutions of older and more experienced countries. It avoided the pitfalls made by them in the past and took the best from each country and adapted this to suit the conditions in South Africa. Other sections of the British Commonwealth of Nations afterwards gave attention to the organization of their national records, such as the Commonwealth of Australia and the Dominion of New Zealand. The most recent recruit is the Colony of Southern Rhodesia, which created an Archives Department by legislation a few years ago. From the three countries, inquiries came to South Africa regarding the system of keeping archives which was being adopted.

Within the last ten years, the archives at Cape Town, Pietermaritzburg and Bloemfontein have been transferred to their buildings with up-to-date equipment and protective devices at a cost of many tens of thousands of pounds. Steps are being taken to provide a separate building at Pretoria, which will house the Provincial archives and contain the records of the Union Government, when old enough for the transfer so laid down by law.

To illustrate the growth of this branch of the service during the last eighteen years, personnel and salary expenditure have increased from a staff of five and an expenditure of £2,800 in 1919, to a staff of 42 and an expenditure of £11,000 in 1937. The number of researchers and visitors and volumes consulted during the last five years indicates a steady and encouraging increase.

The system for the arrangement and classification of the archives in South Africa is that recognized in Europe, and referred to as the 'principe des fonds', in which the system of classification is based on the department of origin. Experience has shown that this is the only sound one.

* Substance of the presidential address to the South African Association for the Advancement of Science, at the Windhoek meeting on July 5, 1937, by Lieut.-Colonel G. Graham Botha, chief archivist of the Union of South Africa.

Colonel Botha described the duties of the archivist in relation to arrangement, classification, inventory and catalogue, and touched upon the physical defence of archives, covering the repository and accommodation, and their moral defence, referring to their reception and arrangement, in which he must study the administrations concerned, their history and organization, and divide them into classes and subdivisions of these; while the secondary duty of the archivist relating to the special requirements of the student covers the preparation of guides, lists, inventories and catalogues of his archives. Full transcripts must be prepared and published under an editor to meet the needs of the student resident at a distance. He also dealt with the problem of selection and destruction.

Finally, in illustration of his contention that archives are the material of history, Colonel Botha outlined from the records preserved in the archives, the history of the national roads in South Africa; the creation of a national road fund, and the constitution of a National Road Board in 1935, of which the story is disclosed in the archives by records of South Africa's early road system and its administration from the seventeenth century onward.

In conclusion, the science of archives may be likened to a venerable sage, who seeks for the authentic traces of man and his doings in the past and, finding them, preserves and jealously guards them. His eyes are glowing with wisdom drawn from the mass of evidence of man's past accomplishments, his failures and successes, as treasured up by him with tender care; ever ready to reach a helping hand to men of the present day in their struggles to move onward the ship of human progress, often doing so with an encouraging smile and reference to the Solomon of Biblical times: "there is nothing new under the sun"; and he appeals insistently to one and all to view the present unfolding of our grand and wonderful universe in the light of the ages gone by.

Science News a Century Ago

Lyell in Germany

WRITING from Weesl on the Rhine on August 29, 1837, to Darwin, Lyell said, "I write this to you, at least I am beginning it, in a steamboat on the Rhine, so make allowance for the tremulous motion. We came in a steamer from Copenhagen to Lübeck, then in a hired carriage to Hamburgh, across the sand and boulder formation of the Baltic, which for the most part we have been on ever since, although we have crossed the Weser, and Ems, and Lippe. The blocks of red syenitic granite, which I hammered away at in Norway, and which I saw there *in situ* sending its veins into the trilobite and orthoceratite schist, have been carried with small gravel of the same, by ice of course, over the south of Norway, and thence down the south-west of Sweden, and all over Jutland and Holstein, down to the Elbe, from whence they came to the Weser, and so on to this or near this. . . .

"This then was already dry land when Holstein, and all from the Baltic as far as Osnabrück or the Teutoburger Wald hills, was submerged. At Bremen I saw Olbers, aged seventy-two, the astronomer who discovered Pallas and Vesta, and at Osnabrück and Münster I met a warm and German reception from men of whom I had never heard, who had read

my paper on Sweden or something else. I mean by German, that kind of frank expression of enthusiasm for science, or of any emotion, which a well-bred Englishman tries to suppress, at least all outward expression of it, from the dread of being thought ridiculous, or of affecting to feel more than he does, or from *mauvaise honte*. If you ever get sick of that fashionable nonchalance which would blush to admire anything, or at least to confess it, I advise you to plunge into Germany, and you will be soon refreshed and brought back to the right tone again, whether it be literature, science, or any other pursuit you are following. . . ."

The First Steam Frigate

ON August 31, 1837, H.M.S. *Gorgon*, the first steam vessel in the Royal Navy designed as a frigate, was launched at Pembroke. Designed by Captain (afterwards Admiral) Sir William Symonds, the Surveyor of the Navy, the *Gorgon* was 178 ft. long, 37½ ft. beam and 1,108 tons burthen by the rule known as Builders' Old Measurement. She was noteworthy not only as being designed as a frigate, but also as being the first vessel in the Navy to be fitted with John Seaward's direct-acting engine, instead of a side-lever engine, by which a considerable saving of weight was effected. The cylinders were placed directly beneath the crankshaft driving the paddle wheels. They were 64 in. diameter with a stroke of 5½ ft., the engine being of 320 nominal horse-power. The boiler pressure was 5 lb. per square inch. The total weight of the machinery, including the water in the boilers, was 276 tons. Service in such vessels was eagerly sought after by far-sighted young naval officers, and among those who served in the *Gorgon* was Admiral Sir Astley Cooper Key, who as a lieutenant exchanged from the *Curapoa* into the *Gorgon* and in doing so spoke of it as almost a change of profession. "Being in a steamer", he wrote, "has given me a much greater interest in the service than I had before, from having, I suppose, an object in view to which I feel myself suited." On another occasion he wrote, "I study De Pambour and Tredgold daily".

The British Association at Liverpool

IN its issue of September 2, 1837, the *Athenaeum*, referring to the forthcoming meeting of the British Association at Liverpool, said that while there had been no doubt as to the really excellent fruits of the morning meetings, the same satisfaction had not been felt regarding the evening meetings, which had been intended for diffusing among the general body of members "some part of the treasures of knowledge collected and purified in each Section". There was therefore to be a change of plan. "The great want of opportunity for cultivating mutual acquaintance and enjoying friendly discussion—a desideratum felt with increased force at every Meeting succeeding the embryo sitting at York—will be met by devoting at least two evenings to a pleasurable Promenade and Conversations in the magnificent apartments of the Town Hall, which the Mayor and Council have most liberally placed at the disposition of the Association. Thus the evenings may offer an agreeable relaxation after the morning work—the men of abstract and practical knowledge may be mingled together, and both brought into friendly intercourse with those numerous friends of the Association who attend the meetings to gather knowledge, and those whom they esteem as leaders of science."

Societies and Academies

G. F. K. NAYLOR: A preliminary note on the occurrence of Palaeozoic strata near Taralga, N.S.W. Recent investigations near Taralga have shown that Palaeozoic sedimentation is represented in that area by Upper Ordovician, Upper Silurian and Upper Devonian strata, their respective ages being determined conclusively by the presence of fossils. The general rock pattern conforms to, and is continuous with, that previously determined in the Goulburn district. An interesting point is the finding of black shale containing *Monograptus bohemicus*, interbedded with highly fossiliferous Upper Silurian limestones. This indicates that the latter are of Lower Ludlow age, and owing to the restricted range of that graptolite, may lead to a more exact correlation of N.S.W. Silurian rocks with British and Victorian occurrences than has hitherto been possible.

A. J. BRON: The detection and estimation of α -phellandrene in essential oils. This paper describes an adaptation of the 'diene' synthesis to the detection of α -phellandrene in small quantities, and its estimation in the presence of *p*-cymene, cineol, limonene or α -pinene.

Forthcoming Events

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (NOTTINGHAM MEETING).

Wednesday, September 1

At 8.30 p.m.—Sir Edward Poulton, F.R.S.: "The History of Evolutionary Thought, as recorded in the Meetings of the British Association" (Presidential Address in the Albert Hall).

Thursday, September 2

At 10 a.m.—Sir William Bragg, O.M., K.B.E., Pres. R.S., Dr. G. Shearer, Dr. J. D. Bernal, F.R.S., J. T. Randall and H. P. Rookby, Dr. A. J. Bradley, and R. M. Powell and W. A. Wood: "X-Ray Methods and Industry" (Symposium: Section A).

Dr. F. L. Pyman, F.R.S., Prof. H. Horlein, Sir Gilbert Morgan, Dr. W. Kikuth and Prof. R. Robinson, F.R.S.: "Some Aspects of Chemotherapy" (Symposium, including Dr. Pyman's Presidential Address entitled "Researches in Chemotherapy": Section B).

Prof. F. A. E. Crew: "The Sex-Ratio" (Presidential Address: Section D).

H. Wolfe, C.B., C.B.E., H. M. Hallsworth, C.B.E. Dr. O. A. Osor and A. D. K. Owen: "Labour Transference" (Discussion: Section F).

Dr. E. P. Poulton: "Heat Production, Nutrition and Growth in Man—Some New Views" (Presidential Address: Section I).

Prof. E. J. Salisbury, F.R.S.: "The Modern Study of Plants in Relation to Education" (Presidential Address: Section K).

H. G. Wells: "The Informative Content of Education" (Presidential Address: Section L).

J. M. Cole: "State Intervention in Agriculture" (Presidential Address: Section M).

Sir Alexander Gibb, G.B.E., C.B., F.R.S.: "Research in Engineering" (Presidential Address: Section G).

Prof. D. Burns, A. L. Bacharach, Mrs. C. M. Burns, Dr. G. E. Friend, Prof. E. Atzler, Prof. S. J. Cowell: "Contribution of Physiology to the Health of the Individual and the Community" (Discussion: Section I).

At 2.15 p.m.—Prof. J. Ritchie: "The Outlook of Natural Science" (Presidential Address to the Conference of Delegates of Corresponding Societies).

Friday, September 3

At 10 a.m.—Dr. G. W. O. Kaye, O.B.E.: "Noise and the Nation" (Presidential Address: Section A).

Prof. C. R. Harington, F.R.S., Dr. K. Linderström-Lang, Dr. W. T. Astbury, Dr. D. M. Wrinch, Dr. A. Neuberger and J. St. L. Philpot: "Protein Chemistry" (Symposium: Section B).

Prof. L. J. Wills: "Pleistocene History of the West Midlands" (Presidential Address: Section C).

Dame Helen Gwynne-Vaughan, G.B.E., Prof. F. A. E. Crew, Prof. R. A. Fisher, F.R.S., Dr. F. W. Sansome, Dr. C. D. Darlington, Dr. P. C. Koller, E. B. Ford and Dr. J. S. Huxley: "Recent Work in Genetics and Cytology" (Joint Symposium: Sections D and K).

Prof. C. B. Fawcett: "The Changing Distribution of Population" (Presidential Address: Section E).

Prof. P. Sargent Florence: "Economic Research and Industrial Policy" (Presidential Address: Section F). Prof. F. G. Bailey and A. P. M. Fleming: "Training of University Graduates for the Engineering Industry" (Discussion: Section G).

Prof. J. H. Hutton, C.I.E.: "Assam Origins in Relation to Oceania" (Presidential Address: Section H).

Dr. Mary Collins: "Tests in Common Use for the Diagnosis of Colour Defect" (Presidential Address: Section J).

Prof. A. M. Carr-Saunders, Sir Frank Fletcher, Mrs. E. V. Parker, M. A. Deedee and Dr. Graef: "Education for the Community" (Discussion: Section L).

L. Holland, J. Macdonald, J. T. Fitzherbert, Dr. S. E. Wilson, C. J. Jones: "Mining Timber" (Symposium: Section K*).

Discussion on "Anthropology and Administration" (Section H).

At 7.30 p.m.—Prof. J. Walton: "Coal and its Origin" (Popular Lecture at Mansfield).

At 8 p.m.—R. Kay Greenwell: "Rivers and Waterways" (Public Lecture at Lincoln).

At 8.30 p.m.—Dr. R. E. Slade: "Grass and the National Food Supply" (Evening Discourse).

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.

TECHNICAL OFFICER AND ASSISTANTS (grades II and III) at the Air Defence Experimental Establishment, Bagin Hill, Kent (September 1).

ASSISTANTS (grade III—electrical engineering and photographic equipment) at the Royal Aircraft Establishment, South Farnborough, Hants.—The Chief Superintendent (September 3).

RESEARCH ASSISTANT IN CHEMISTRY (radioactivity) in the University of Manchester—Prof. M. Polanyi (September 6).

DEMONSTRATOR IN HISTOLOGY AND EMBRYOLOGY in the Royal Veterinary College and Hospital, Camden Town, London, N.W.1.—The Secretary (September 7).

UNIVERSITY ASSISTANT IN AGRICULTURAL BOTANY in the University of Aberdeen.—The Secretary (September 14).

PROFESSOR OF BOTANY in the University College of the Orange Free State, Bloemfontein.—The Rector (September 30).

EXAMINER (Chemist) in the A.I.D. Test House, Kidbrooke (Non-Metallic Material Section, Oils and Petrols Sub-Section)—The Secretary [S.2 (d)] Air Ministry, Kingsway, W.O.2 (October 31).

WATERWORKS ENGINEER for the Government of Nigeria—Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quote M/5346).

LECTURER IN GEOLOGY in the University of Rangoon.—The Secretary, Universities Bureau of the British Empire, 88a, Gower Street, W.O.1.

PROFESSOR OF ANATOMY in the University of Melbourne.—The Secretary, Universities Bureau of the British Empire, 88a, Gower Street, W.O.1.

Official Publications Received

Great Britain and Ireland

Memoirs of the Cotton Research Station, Trinidad. Series B: Physiology, No. 10: The Effects of Light and of Oxygen on the Uptake of Sugar by the Foliage Leaf. By B. Phillips and T. G. Mason. Pp. 231-237+2 plates. (London: Empire Cotton Growing Corporation.) 2s. 6d. [48]

Technical College, Bradford. Diploma and Special Day Courses, Session 1937-1938. Pp. 261+21 plates. (Bradford: Technical College.) [48]

Processes of Organic Evolution

ONE of the difficulties about organic evolution is that it has not been and probably cannot be demonstrated in a strict sense, and although the indirect lines of evidence converge with such unanimity upon the probability of the theory that the scientifically trained mind is convinced, a loophole for doubt remains to the multitudes who must rely upon the dictum of authority one way or the other.

The evolutionist who rests upon his oars, convinced that the stream is running with him, misjudges the set of at any rate one considerable part of the current. "Le problème de l'Evolution paraissait plus près de sa solution, il y a quarante ans, que maintenant", wrote Prof. Caullery, and the critical examination of "le Transformisme" is a noticeable activity of French thought at the moment. In America the anti-evolution or Fundamentalist position is well entrenched. There in June the monthly magazine *Evolution*, described as "A Journal of Nature; For Popular Education in Natural Science, to Develop the Open Mind", reappeared after a lapse of five years due apparently to lack of supporters interested in open minds; and the editor, after interviewing 20,000 persons, says, "I am more convinced that there is a need and a real field for *Evolution* than I was before I started." He was advised if he wished to make a commercial success of his journal to change *Evolution* to some "less offensive" name. In Great Britain the feeling against evolution lies rather under the surface, but it exists, and we recall the surprise with which we listened to the announcement of a University student that she did not propose to answer any examination question upon evolution, because neither she nor her parents believed in it!

When, therefore, Sir Edward Poulton in the course of his charmingly reminiscent presidential address to the British Association on "The History of Evolutionary Thought, as recorded in Meetings of the British Association", which is printed in the Supplement to this issue of *NATURE*, passed lightly over "the subject of organic evolution itself, *as generally accepted*" (our italics), he spoke truly of his scientifically minded audience, for he recalled only one example of opposition to a belief in organic evolution, and that was at the first meeting he attended, in 1881. But the swamping of two thousand scientific workers by a week-end influx of trippers during the Blackpool meeting gave perhaps a rough indication of the number of believers to the masses who do not understand evolution, who do not care, or who are actively or passively opposed. The position, however, is gradually changing. The idea of evolution, as understood to-day, is comparatively new, and the natural death of prejudice, together with the diffusion of knowledge in school and college, and particularly through the far-reaching voice of the radio, are paving the way for the general recognition of a process the idea of which has become a commonplace of scientific thought.

Evolution rests upon two primary or basic factors: the vital characteristic of organisms to produce variations, and the heredity which makes possible the establishment or perpetuation of these variations. Both aspects have been discussed at meetings of the British Association, but the tendency has been for debate to centre upon the secondary or guiding factors, the means by which the course of evolution has been directed. Here there has been controversy enough since natural selection took the field, and particularly since that

discussion in 1887 at Manchester upon "The Hereditary Transmission of Acquired Characters" in which Weismann took part, who all but strangled the idea of the inheritance of acquired characters at its resuscitation.

Into this controversy, Sir Edward Poulton in his address threw himself with gusto and with many recollections of the great debaters of the past, for he himself during the last fifty years has been in the forefront of the battle. Having nailed his colours to the mast, he picked here and there from the meetings of the last half-century opinions or evidences in favour of the efficacy of natural selection, notably from Prof. Alfred Newton and Canon Tristram, and against the inheritance of acquired characters by Ray Lankester.

The recalling of these contentions is a reminder of the difficulty of adducing real proof of any theory of evolutionism, and of the assumptions which the early followers of Darwin permitted themselves. Take the quoted case of Canon Tristram's larks of North Africa, where a sandy area has a long-billed, and a rocky district a short-billed species. The assumption made was that "the shorter-billed birds would be at a disadvantage in obtaining food from sandy areas but at an advantage among the rocks where strength is required". A plausible assumption, but, unbacked by a thorough analysis of the food consumed and the food available, no more than an assumption.

Compare Tristram's evidence with the more complete observation of bill structure made by Joseph Grinnell in Lower California, where in a peculiar area of meagre rainfall and high atmospheric humidity (a humid desert) he found that lesser size of bill was a common feature of birds as different as flycatchers, finches and woodpeckers. It is difficult, but not impossible, to assume that birds of feeding habits so diverse could all benefit by exactly the same kind of modification, so that, for each, environment should select similar variations. It is even more difficult to make the assumption, since other common modifications occur in all these birds, such as deeper coloration and certain proportions of wing and tail. What seems to be clear is that environment has been at work, and has induced the living organism to respond in similar manner, no matter that the stocks were of different pedigree. But does that imply the inheritance of acquired characters? Even here more evidence about food and habits is necessary before any valid conclusion can be drawn.

So it is, unfortunately, with most of the observations adduced in support of particular means of evolutionary progress. Sir Edward Poulton mentioned the work of Weldon and Thompson on the influence of impurities in the sea at Plymouth upon the frontal width of the common shore crab, which, it was suggested, ensured that the water flowing over the respiratory surface was more efficiently filtered. But these observations and experiments, beautifully convincing as they appear to be at first sight, have been criticized so reasonably and ably that the conclusions cannot be accepted with any confidence.

The fact of the matter is that the story of evolutionary thought shows, as regards the processes of evolution, that the first flush of enthusiasm, with its easy evidences and somewhat uncritical observations, has passed, and that science will be satisfied only with careful records or controlled experiments safeguarded so as to convince the open but critical mind. To this new evidence the naturalist, as well as the experimenter, must make his contribution; but for the naturalist also the conditions become more stringent, and, to take another example, the statistical analysis in relation to protective patterns of food taken by a bat will be regarded as valid only when viewed in relation to the abundance of the food items and their availability at the time and place of the bat's collecting; and that is no simple series of observations.

In another way, investigation into the modes of evolutionary progress is likely to undergo modification. Few biologists, nowadays, doubt that natural selection has played a great part in guiding that progress; it is taken to be, as Bateson took it, self-evident. But natural selection merely plays with variations created by the organism; the vital problem lies deeper. Does the vitality of the organism, a thing of wondrous properties, really express itself in non-significant variations left entirely for Nature to carve into line, or does it respond more directly to the environment in such a way that subsequent generations share in the response, or does it even more directly handle its own fate by striking out in determinate lines of its own—it being postulated, of course, that whatever the source of the variations they must afterwards come under the pruning hook of natural selection? There seem to lie the evolutionary problems of the immediate future for the eager student of biology.

Ancient Fauna and Early Man at Bethlehem

THE report on the bone-bearing beds of Bethlehem by Miss E. W. Gardner and Miss D. M. A. Bate, appearing in this issue of *NATURE* (see p. 431), summarizes the results of three years' excavation on a site situated in the highest part of Bethlehem on the highest point of the Judean arch, of which the importance for the physiography and palaeontology of Palestine was established in 1934 by the discovery of the fossil remains of an elephant, the first evidence of the former existence of this extinct species in this geographical region.

Since that date, as Miss Bate shows, the Bethlehem bone beds have yielded evidence of an extinct fossil fauna, which is not only almost entirely new to Palestine, but is also of earlier geological age than any found there hitherto. Further, from the gravels of these deposits have come 'flints', which may prove to be the earliest trace of man in Palestine.

The character of the geological deposits in which the fossil fauna occurs, as is indicated in Miss Gardner's report, is such as to add considerably to the importance of the discovery. The bones were found in water-borne gravels deposited on a cemented scree, or breccia, weathered sub-aerially. The lie of the deposits is such that it is evident that they cannot have been laid down originally in the position in which they are now found. While Miss Gardner exercises a wise discretion in refraining from any premature conjecture as to their origin before excavation is complete, she goes so far as to suggest that the condition of the deposits may be due either to the collapse of the original floor or to the filling of a funnel-shaped hole. These conditions are of prime importance in pointing to movement and physiographic changes, indicating a considerable antiquity.

While the evidence of geology, pending further investigation, is thus reticent as to questions of origin and chronology, the aid of other branches of investigation—archaeology and palaeontology—is invoked to give evidence on the question of dating; and here is brought forward what to many certainly will seem the most startling evidence from this investigation. Miss G. Caton-Thompson, whose experience in dealing with early Stone Age forms in the East entitles her to speak with authority, has found in the vast multiform assemblage of cherts in the gravels, showing

evidence of subjection to a variety of forces, a number of pieces which she holds it difficult to explain except as humanly fashioned tools. Drawing a pregnant comparison with Mr. Reid Moir's 'artefacts' from the Red Crag of Foxhall and the sub-Crag detritus bed flints of Bramhall, she regards many of the Bethlehem 'artefacts' as conforming closely "in shape and edge trimming to the classic type of Harrisonian eolith". She goes on to point out that this is the first time such evidence has been found in a sealed deposit in Palestine—evidence which "is less easily reasonably to explain as the accidental work of natural forces, than as the deliberate experimental work of man in remote pre-Chellean times".

The archaeological evidence, thus possibly the earliest indication of man's appearance in Palestine, gains in significance when brought into relation with the interpretation of the palaeontological data, as regards geographical distribution and dating.

The crucial point is the occurrence of the diminutive form of horse, *Hipparion*, previously known from various deposits in Asia of Tertiary age, but recently reported from the Pleistocene of India, and now well known from the Pleistocene deposits of East Africa. With it goes the evidence of other members of the Bethlehem fauna, also pointing to an affinity with Asiatic forms of like age. Miss Bate, therefore, in summing up, concludes by suggesting that the Bethlehem fauna in origin is Asiatic and that its age is not later than early Pleistocene, adding that it provides a faunistic link for this period between Asia and East Africa.

It need scarcely be said that if Miss Caton-Thompson's tentative acceptance of the specimens she has selected as artefacts is well grounded, this discovery at Bethlehem will prove of transcendent importance in the consideration of the problem of the distribution of early man. It would be premature to enlarge on this aspect before the specimens have received further expert consideration; but it may be pointed out that these excavations serve to reassert the growing importance of Palestine for the problems of early man, already demonstrated in Miss Garrod's excavations and the investigations of Sir Arthur Keith and Mr. T. McCown on the physical characters of the early forms of man from Mount Carmel.

Scientific Aspect of Chinese Glazes

Chinese Ceramic Glazes

By A. L. Hetherington. (Courtauld Institute of Art.) Pp. x+76+14 plates. (Cambridge: At the University Press, 1937.) 10s. 6d. net.

THIS concise and simply written treatise, which embodies an amplification of a series of lectures given recently by the author at the Courtauld Institute of Art, links together scientific facts and archaeological knowledge concerning the chief glaze effects produced by Chinese potters during a period extending over some two thousand years.

A preliminary chapter is devoted to general considerations on the nature of the glazes, slips and earthenware bodies employed by successive generations of Chinese potters, on the effect of oxidation and reduction upon the colouring materials used in glazes, and on the modifications produced in these colour effects by the relative proportions of acidic and alkaline constituents in a glaze.

It is a striking testimony to the long-sustained art of the Chinese potter that nearly all his earlier colour effects were achieved by the use of only two metals, iron and copper. The old and fascinating 'iron' story, well exemplified by the ceramic ware shown at the Chinese Exhibition in London of 1935, explains the great variety of colour tints induced in glazes by varying amounts of the three iron oxides. Temperature conditions of firing and the presence of alkalis affect the final colour very appreciably. The pale blue ferrous oxide glaze of certain translucent porcelains dating from Sung times, on spectroscopic examination in the electric arc has shown persistent evidence of the lithium spectrum, a fact which points to the

presence of lithia-mica in the original felspathic glaze (Chinese petuntse).

The range of colour produced by ferric oxide is even more extensive than of ferrous oxide, and, as the author has shown experimentally with boric acid and alkali borates, is greatly affected by the acidity or alkalinity of the glaze constituents.

The 'copper' story is equally remarkable, for the colour effects produced by cupric oxide and its reduction product, colloidal copper, are of the highest artistic merit. The author discusses in detail the scientific principles underlying the production of *sang-de-bœuf*, *chün-yao*, *flambé* and *peach-bloom* glazes, this section being illustrated by several coloured plates.

Under the heading of other glaze effects, a section is devoted to the use of cobalt, manganese and gold. The first two metals are utilized as colouring materials in the form of their oxides; whereas the *famille rose* wares owe their characteristic tints to the use of minute amounts of colloidal gold. This chapter contains also references to opalescence and to crackle, the latter effect being a special and popular feature of Chinese porcelain, which often develops on ageing a delayed crazing or double crackle.

This book, which contains fourteen plates, concludes appropriately with an informative glossary of Chinese and other technical ceramic terms. A selected bibliography is also included of works on Chinese ceramics, among which are to be noted two earlier publications by Mr. Hetherington on the porcelain factories and ceramic wares of China. To these authoritative treatises the present book forms a useful complementary volume.

G. T. MORGAN

The Future of Statistical Mechanics

Statistical Mechanics:

the Theory of the Properties of Matter in Equilibrium. By Prof. R. H. Fowler. Second edition, revised and enlarged. Pp. x+864. (Cambridge: At the University Press, 1936.) 50s. net.

PROF. R. H. FOWLER'S monumental work on statistical mechanics has, in this the second edition, in his own modest words, been rearranged and brought more up to date. But the new volume is much more than a revision, in that it is explicitly based on quantum mechanics from the outset; the first dynamical equation found written in

the formal presentation is a wave-equation. Prof. Fowler states in justification that although classical mechanics is used to derive the quantum mechanics by a process of generalization. "once the laws of quantum mechanics have been thus guessed, as they must be before we can discuss the theorems of statistical mechanics, quantized systems naturally come first. In 1935 this attitude hardly needs apology". In consequence of this, the concluding chapter of the first edition, dealing with quantum statistics, has been incorporated in the new exposition from the start, and what is

effectively the opening chapter is now doubled in length. Otherwise there is no change of general structure. But a comparison of the two editions shows that the chapter of the first edition entitled "Thermionics" is now more than four times as long, and contains a treatment of the electron theory of metals and of semi-conductors; that the chapter on dielectrics and magnetic constants has been similarly extended, and now includes an account of ferro-magnetism; lastly, there is a new concluding chapter on "co-operative" and other phenomena. The number of references is almost doubled. It is difficult to over-estimate the amount of work involved in thus re-writing and extending what was already an encyclopædic work.

The fascinating introductory chapters raise a number of interesting questions in the mind of the reader. One is that of the physical origin of the extreme generality of statistical mechanics. It is a logical structure, based on certain laws of quantum dynamics which are themselves inductions from certain special sets of phenomena; but, as Prof. Fowler remarks, the structure is "not visibly constructed to fit the facts", that is, the facts concerning phenomena in the domain of large numbers of interacting systems. "Results have been at each stage deduced from the general theory, and checked by comparison with experiment". But the comparisons with experiment are far more than a checking of the results. The comparisons with macroscopic thermodynamics do more than test the formulæ derived: they permit the *identification* of symbols introduced abstractly, as part of the mathematical apparatus, with entities known physically in a different guise. One example is the identification of the abstract symbol Ω with the factor $e^{-1/kT}$, where kT is known physically from the more concrete dynamical theory of gases; a second is the identification of a symbol with the thermodynamic entropy; a third is the identification of a set of symbols with the thermodynamic partial potentials. The structure exists independently of these identifications: the identifications permit us to recognize the correspondence of the abstract scheme with Nature. Some of Gibbs's theorems in pure thermodynamics were known as logically unexceptionable results before the corresponding phenomena were fully studied. How comes it that statistical mechanics is in an even more powerful position?

It is impossible to answer such a question in a review. But it may be recalled that a necessary, if not a sufficient, condition that a logically correct structure shall 'correspond' with Nature is that it shall also be epistemologically correct. There must exist some ground for our direct acquaintance with the entities introduced, in the sense used in the theory of knowledge. In some way, statistical

mechanics must be, also, epistemologically 'sound'. Yet in the first dynamical equation used by Fowler, already mentioned, there occurs the symbol ψ , whose epistemological status is, to say the least, doubtful. This dynamical equation of motion is, however, preceded by a dynamical *statement*, concerning the structure of a Hamiltonian, based on classical mechanics, all the terms in which are assumed directly knowable by observation. The Hamiltonian, in this case that for an ideal linear oscillator, is the *definition* of an oscillator as required for the purposes of the theory. In other words, we make clear to the reader what we are talking about by tacitly supposing a correspondence between the crude physical picture of an oscillator and the terms in a mathematical expression. Out of such axiomatic definitions mathematical physics arises, but here there is a jump from the axiomatic definition to the associated wave-equation. In cruder forms statistical mechanics existed before wave-mechanics was known, though it still had to make certain appeals to a quantum theory. There would seem possibly to be scope for a treatment which is confined to the properties of assemblies of large numbers of systems and originates from axiomatic definitions concerning such alone.

Prof. Fowler mentions the well-known consideration that the fact that a particular mechanism leads to a state of complete equilibrium in agreement with experimental facts is no evidence for the particular mechanism discussed. It is merely evidence that the laws of the mechanism have been correctly and consistently written down. It follows that there are certain restrictions on the laws of the mechanism, for they might have been incorrectly written down. An example of such a restriction is the principle of detailed balancing. It would be interesting to know the complete set of restrictions which statistical mechanics imposes. Are they merely that the mechanism must obey the laws of dynamics assumed as a basis for statistical mechanics? If not, how much less restrictive a dynamics is all that is necessary?

Prof. Fowler takes a somewhat pessimistic view of the future of statistical mechanics when he writes that "developments in the near future seem likely to consist mainly of applications to more and more complicated models . . . designed to account for more and more subtle properties of matter in equilibrium". Two possible lines of development offer themselves, both suggested by remarks of the author himself. One is in the statistical mechanics of non-enclosed assemblies. Prof. Fowler writes: "All assemblies whose equilibrium states can be discussed are necessarily *enclosed* assemblies. An unenclosed assembly to which all space is accessible does not in general

possess an equilibrium state about which anything significant can be said". But is this true? It would be highly interesting to obtain theorems of statistical mechanics valid in an unenclosed finite space or in an expanding sphere of inaccessible boundary. The latter case would have the added charm that the number of systems that it would be necessary to consider would be truly infinite and not merely 'large'.

Again, the part of an assembly which for the greater part of time has practically an independent existence is called a *system*, and statistical mechanics is in part the study of the equilibrium states of assemblies of such quasi-independent systems. But the dynamics of a system, still more of an assembly, seems to be an aspect of the relation of such an assembly or system to the rest of the matter in the universe; the laws of dynamics are derivable from a study of such relationships. If so, in what sense are the systems 'independent'? They are formally independent *given the laws*, but not independent when the dynamical laws themselves are subject to examination. This gives one an uneasy feeling that the present status of statistical mechanics is uncertain, and that a thorough-going treatment would indeed contemplate at one blow the interactions of *all* the particles in the universe. Is it not possible that some features of the distribution of spiral nebulae in the whole universe, their mean separations, masses and proper motions, could be studied by the methods of statistical mechanics?

The other line of development is the problem of steady states which are not equilibrium states. Consider, for example, the one-dimensional flow of heat through a gaseous assembly maintained in a steady non-isothermal state by the imposition of plane boundaries kept at given unequal temperatures. The gas must settle down into a steady state of maximum entropy subject to the given boundary conditions. Such a non-equilibrium steady-state is composed of independent systems interchanging energy, and indeed handing on energy across each plane section at the same rate. If, therefore, the boundary conditions of given temperatures could be stated in molecular language, the whole problem could be treated as a maximum or average problem by the usual methods of statistical mechanics. The trouble comes in in the precise formulation of the boundary conditions at the two ends in kinetic language when they are merely given in thermodynamic language. Since we know that the whole phenomenon is a 'transport' phenomenon, involving the sizes or free paths of the systems, we cannot hope to solve the problem without some discussion of mechanism. But the mechanism that is relevant is surely mainly the mechanism of transfer at the two end-boundaries, and it is just because the problem suggests the hope of a statistical calculation throwing light on mechanism that this problem is so attractive. I believe the problem to be in fact tractable.

Plant Protection

The Scientific Principles of Plant Protection: with Special Reference to Chemical Control. By Dr. Hubert Martin. Pp. xii + 379. (London: Edward Arnold and Co., 1936.) 21s. net.

IN these days of selected races, artificial fertilizers and other specialized conditions, plants are proving alarmingly susceptible to attack, and there has in consequence grown up a technique regarding their protection and a science to correspond where mycologist and entomologist, chemist and physicist, meet on equal ground. 'Plant doctors' abound and there are numerous remedies varying from the spraying with copper preparations, which make the vineyards of the Rhine look so unnatural, to the use of other and beneficial insects to control the malevolent. The late Prof. H. E. Armstrong pictured for us the golfer salting his way over the greens with copper arsenate followed by the bodies of earthworms.

Like Sir Albert Howard, he preached the supreme value of good nutrition based on an organic compost and believed that the outbreaks of disease are due to lack of organic manure; that, in short, properly fed plants, like properly fed animals, would be largely resistant to disease and the road to health is through organic protective foods.

Evidence is accumulating in favour of this view and it is one which plant growers cannot afford to neglect in the future. In the meantime, farmer, fruitgrower and gardener have to face the ravages of blights and pests on their new varieties of plants, due in part to the fact that massing favours the spreading of chance infection: it is a fact that the more intensive the cultivation the greater the risks. Most of these were practically unknown a few years ago and so there has been an urge to find remedies to combat them. Dr. H. Martin, of Long Ashton, one of the most active and successful

horticultural research stations, has long been regarded as an expert on the subject and the present book is a second edition, though since it has been rewritten and reset, since every phase of the subject has developed during the intervening eight-year period, it may virtually be regarded as a new book.

It is a well-balanced production with the material arranged in logical order—plant resistance is in the foreground, the factors which make plants susceptible come next and then follow several chapters on biological control, fungicides and insecticides; weed killers, fumigants, seed and soil killers, complete the list, though Dr. Martin has also something to say about traps.

A goodly list of chemicals is paraded before our eyes, as numerous as the nostrums in the druggist's

shop, and it is no wonder, in the words of Sir Daniel Hall, that "great commercial firms have embarked upon the manufacture of suitable materials for sprays and washes and have themselves promoted investigation in their desire to produce useful remedial preparations".

At the foot of the plants is the soil, which receives more than its share of the remedies, with an effect on its own fauna and flora which can only be imagined. The worms certainly object, but to-day Darwin's famous book on earthworms is out of date, and probably green-keepers do not read it.

The fact that the other side of the picture has been emphasized here must in no way be allowed to detract from the excellence of Dr. Martin's book or the economic importance of the application of the methods he describes. E. F. A.

Gases and Metals

Gases and Metals:

An Introduction to the Study of Gas-Metal Equilibria. By Dr. Colin J. Smithells. Pp. vii + 218 + 4 plates. (London: Chapman and Hall, Ltd., 1937.) 18s. net.

THE behaviour of metals towards the common gases is important to many industries, but investigators who have been concerned with its various aspects have had little contact with each other, and the subject has not hitherto been adequately treated from a theoretical point of view. Dr. Smithells's book is therefore extremely welcome, and its wide scope and original outlook make it a most valuable addition to metallurgical literature.

The work is divided into three chapters, which deal respectively with the adsorption of gases on the surface of metals, the diffusion of gases through metals, and their solution in metals. In each chapter there is a short general introduction and a brief description of the experimental methods, followed by a comprehensive survey of the most reliable results. No emphasis is placed on technical considerations, the data being discussed with the single purpose of defining the general laws which are obeyed, with the view of gaining an insight into the physical nature of the processes.

A sharp distinction is made between physical adsorption, which depends on van der Waals's forces alone, and activated adsorption, in which binding forces of a stronger nature are involved. Much importance is attached to the observation that only those gases which undergo activated adsorption by a given metal can dissolve in and

diffuse through it, from which it is concluded that activated adsorption is a necessary preliminary to diffusion and solution, and that for all these processes some degree of chemical affinity between the gas and the metal is necessary. This thesis is elaborated in the second chapter, which contains the results of the author's and Ransley's work on diffusion, and is the most vigorous and satisfying part of the book.

In the section dealing with solution, ample recognition is given to the work of Sieverts and his collaborators, and the absorption of hydrogen by palladium, which bulks so disproportionately in the literature, is relegated to its proper place as a somewhat unusual borderline case.

This chapter contains a most valuable collection of data, but more is known of the relations between compound gases and metals than appears in this account, and the ferrous metallurgist, in particular, will feel that the equilibria which control the refining of molten steel, and its carburization or decarburization in the solid state, have received less attention than they deserve. Yet in the present state of knowledge, these relations could not have been described in the comprehensive style accorded to the rest of the book. If the metallurgist finds that reactions between compound gases and metals have not been considered as fully as their practical importance would lead him to expect, the omission will come as a salutary reminder that the experimental work which would render a satisfactory treatment possible has, for the most part, not yet been done.

N. P. A.

La civilisation Ainou et les cultures arctiques
Par Prof. George Montandon. (Bibliothèque scientifique.) Pp. 273+48 plates. (Paris: Payot et Cie., 1937.) 40 francs.

PROF. MONTANDON visited the Ainu of Yezo, or Hokkaido as the Japanese now term it, in 1919. On his return he brought back a great stock of observations and an ethnographical collection, now housed in the Trocadéro in Paris, which one of the foremost authorities on the Ainu at that time pronounced to be the most complete that had ever left the island. In publishing the results of his observations in a volume which appeared not long after, Prof. Montandon promised that a more extended study of Ainu civilization would follow. This promise is fulfilled in the present volume, in which the author has reviewed and analysed critically in the light of his own observation all the information available relating to the culture of this primitive and isolated outpost of the white race.

The study falls into two parts. In the first part, Ainu civilization is described in detail as a unitary manifestation of cultural development. In the second part it is brought into relation with the cultures of the various peoples of northern Asia—Yakut, Yukagir, Gilyak, Eskimo, etc.—and as a result of an analysis of the distribution of cultural traits, an attempt is made to arrive at an estimate of the character of the original Ainu culture. As might be expected, Prof. Montandon's conclusion is that everything in Ainu civilization which can be assigned to an Ainu origin is of extremely primitive character, and belongs to the stage of the food-gatherer and the primitive hunter and fisher. All else is of extraneous origin; this, perhaps, might throw light on the remarkable distribution of the Ainu blood groups, which in its combination of mixed characters Prof. Montandon finds disconcerting.

Prof. Montandon's work is a valuable contribution to the critical literature of ethnology, as well as a welcome survey and record of a civilization which in recent years has suffered much change.

The Development of Modern Medicine: an Interpretation of the Social and Scientific Factors Involved. By Prof. R. H. Shryock. Pp. xv+442+8 plates. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1936.) 18s. net.

THE object of this fascinating work, the author of which is professor of history at Duke University (Carolina), is to portray certain major aspects of medical development against a background of intellectual and social history in general from the commencement of the seventeenth century down to the present time. In the eighteenth century it is shown that physics at first did not keep pace with physiology, and it was not until the latter part of this century and the beginning of the nineteenth that medicine began to make further progress. An important step in advance was the successful attempt to correlate clinical and post-mortem observations, in which Boerhaave, Haller and most of all Morgagni were pioneers. The second half of the eighteenth century

was notable for contributions made to public health, such as the establishment of hospitals and dispensaries, child welfare, the control of drunkenness, work on naval and military hygiene, vaccination and other sanitary reforms.

Among the more important advances in modern times stress is laid on the collection of statistics, the influence of French medicine in Europe and the United States, medicine in Germany, preventive medicine and the economic aspects of medical practice.

Materie und Strahlung (Korpuskel und Feld)
Von Prof. Dr. Ludwig Hopf. (Verständliche Wissenschaft, Band 30.) Pp. viii+162. (Berlin: Julius Springer, 1936.) 4.80 gold marks.

IN some respects, this is a remarkable little book. The preface warns the reader that it is more difficult to present a tolerable account of modern physics without mathematics than with them: furthermore, he must not expect easy going. The theme throughout is the 'field' and corpuscular aspects of matter, and, very properly, this leads up to a climax in the more recent attempts at a synthesis by Heisenberg, and by those concerned with electron waves.

The author's treatment is naturally at its best in the earlier chapters dealing with classical physics. Here, the use which is made of diagrammatic representation appears to great advantage, especially for the gas laws, Brownian movement and electromagnetism. In quantum physics and wave mechanics, wherein direct appeal to the eye is scarcely possible, the method is perhaps not quite so happy, since the writer depends to a great extent upon direct illustration.

The philosophical outlook is characteristic and stimulating; it is woven into the fabric of the book with considerable skill. Altogether, this is a type of contribution to the literature of physics seldom seen in Great Britain, and on that account alone well worthy of careful study.

F. I. G. R.

Die medizinisch-naturphilosophischen Aphorismen und Kommentare des Magister Urso Salernitanus
Nach Handschriften Lateinisch und Deutsch herausgegeben von Rudolf Creutz. (Quellen und Studien zur Geschichte der Naturwissenschaften und der Medizin, Band 5, Heft 1.) Pp. 192. (Berlin: Julius Springer, 1936.) 26.60 gold marks.

IN addition to an introduction by Dr. Paul Diepgen, professor of the history of medicine in the University of Berlin, this volume contains the aphorisms on medicine and natural philosophy of the thirteenth century physician and ecclesiastic Urso of Salerno, otherwise known as Magister Urso, followed by his commentaries in the Latin text. Dr. Rudolf Creutz has provided a full German translation of the aphorisms and an abbreviated translation of the commentaries. The historical significance of Urso, as Prof. Diepgen points out, lies in the fact that he deals with the same problems as Arnold of Villanova in the fourteenth, and Paracelsus in the sixteenth, centuries. All three writers were penetrated with Platonic and neo-Platonic ideas and reconciled their religious views with their outlook on natural science.

Observational Evidence for the Distribution of Matter in Space

By J. H. Reynolds

IT is often found necessary by mathematical physicists to make some generalized assumption which in detail is obviously not in accord with experience and observation. This procedure is, of course, quite legitimate, and much important work has been done with such an assumption implicit throughout; and so long as it is recognized that it is still no more than this when the mathematical work is done, no exception can be taken. But when a mathematical assumption is brought down from its idealized condition to a pedestrian 'fact of observation', it is time for the 'fact of observation' to be put through its paces.

Such has happened quite recently in the columns of NATURE to the assumption that matter is uniformly distributed throughout space. It is a very desirable condition for the mathematical physicist to postulate, as it is impossible to work with an irregular distribution; and within the limits mentioned, it has been made the basis of some very interesting and far-reaching researches. But it is now stated that it is an observed 'fact', based on the equable distribution of the 'spiral' nebulae in space, and it is this statement which requires verification.

Fortunately, the observational material which is now available is sufficiently complete and homogeneous for us to form definite conclusions as to the spatial distribution of the spiral nebulae, and those of the same class which show no spiral form and are known as elliptical and irregular nebulae. This observational material, however, is limited to something over a thousand objects, and comes to an end at some distance roughly corresponding to 13×10^6 light years. Beyond this limit it is neither complete nor homogeneous, and it has only been possible to investigate selected regions photographed with the great American reflectors.

There are two criteria which can be adopted for estimating the distances of the nearer extragalactic nebulae—the angular diameters and the integrated magnitude of luminosity. Both are subject to a considerable degree of uncertainty, for there is known to be a large spread in linear dimensions and in integrated brightness. This is apparent in the nearest two spiral systems, the Andromeda Nebula and M33. The first is condensed into stars in the outer regions with a patchy background of hazy nebulosity, the inner parts consisting of bright nebulosity increasing greatly in

luminosity to a star-like central nucleus. The diameter of the major axis of the apparent ellipse on reflector plates is 160'. M33, on the other hand, is much more stellar in general composition and only the central regions are nebulous, with little increase of brightness in the nucleus. The major axis is 65' on reflector plates. (The angular dimensions are those measured visually on negatives exposed in large reflecting telescopes. It has been found that these dimensions are considerably increased if recording microphotometers are used. The excess usually consists of very faint and featureless nebulosity.)

From the criterion of the Cepheid variables found in the outer regions, the distances of both can be estimated with reasonable certainty at between 700,000 and 800,000 light years (about 240 kiloparsecs) in each case, although the diameter of the Andromeda Nebula is two and a half times that of M33.

The difference between the integrated magnitudes of the two systems is still more striking. According to a list of extra-galactic nebulae by Shapley and Ames (*Harvard Coll. Ann.*, 88, No. 2), the integrated magnitude of the Andromeda Nebula (M31) is about 5, M33 being 8. The ratio between one magnitude and the next being 2.512, M31 as a whole is sixteen times as bright as M33. But even this relative luminosity seems to be an understatement, for in a recent paper by Redman and Shirley (*Mon. Not. Roy. Ast. Soc.*, 97, 416) the integrated luminosity of M31 is given as 3.5 mag. (photographic), while the surface brightness at the centre is at least 14.8 mag. per square second of arc, compared with the fainter 20.3 mag. per square second of arc at the centre of M33. The dispersion in absolute magnitude can therefore be much greater than the dispersion in linear dimensions, judging from these two systems at about the same distance. For this reason I have preferred the criterion of angular diameter in my work on the spatial galactic distribution of the nearer systems.

In this kind of research there can only be one division of the celestial sphere which is fundamental, namely, that in which the great circle of the galaxy forms the equator, and all investigations into the distribution of the extragalactic nebulae have been based on this. Let us take first of all the extragalactic systems which lie within a radius of 700 kiloparsecs (2.275×10^6 light years).

If we include the two Magellanic Clouds and the irregular nebula N.G.C. 6822, we find within this radius nine systems are in the south galactic hemisphere against four in the north. This result is based on Cepheid variables in the nearer objects and the detection in the more distant nebulae of faint stars which Hubble assumes cannot exceed -6 absolute magnitude: in the case of N.G.C. 55, 247 and 300, photographed at the Helwan Observatory, Egypt, the distances are based on large angular diameters only. Seven of the nine southern systems are also probably nearer the galactic system than any of the four northern objects.

Past a radius of 1,000 kiloparsecs (3.25×10^4 light years) the large preponderance of systems

The small scale brought the linear size of the nebulae on the plate down to something near that of star disks, which could be directly compared with stars of known magnitude. It was assumed that the plates gave essentially complete information as to the nebulae brighter than 13.2 magnitude, and this information was comprised in a detailed catalogue of 1,249 objects. It was further assumed that all these were included within a radius of 3,000 kiloparsecs; this estimate was based on integrated magnitudes alone, but if recorded angular diameters of the spiral class are taken as a criterion of distance instead, it would appear that this estimate would have to be increased to at least 4,000 kiloparsecs.

Fig. 1.

DISTRIBUTION OF THE BRIGHTER EXTRA-GALACTIC NEBULAE IN THE NORTH AND SOUTH GALACTIC HEMISPHERES. OPEN CIRCLES REPRESENT THE 291 NEBULAE BRIGHTER THAN PHOTOGRAPHIC MAG. 12; DOTS REPRESENT THE 734 NEBULAE OF PHOTOGRAPHIC MAGNITUDE 12-13. FROM *Harvard College Annals*, 88, No. 2 (1932).

passes to the north galactic hemisphere. They are now so far distant that no stars can be detected even with the 100-inch reflector at Mt. Wilson; the criterion of integrated luminosity has therefore been adopted both in Hubble's work and in Shapley's investigations at the Harvard College Observatory. The luminosity ratio between one magnitude and the next being 2.512; this represents a difference in distance of 1.585 per magnitude.

It is to Shapley and Ames that we owe the most complete and reliable evidence as to the galactic distribution. The whole sky was photographed with two 2-inch lenses at centres regularly spaced, the scale of the plates being 10 minutes of arc to the millimetre, and the magnitude limit for 90 minutes exposure lying between 13.5 and 14.0.

The plates included those nebulae of large angular diameter above $10'$ which lie within 1,000 kiloparsecs and have already been dealt with, and when all the nebulae brighter than mag. 13 were plotted in the two galactic hemispheres it was found that those in the northern hemisphere were just about double the number of those in the southern. Not only so, but also the effect of longitude found in previous investigations without such complete information was fully confirmed. The diagram here reproduced (Fig. 1) is from Shapley's paper, and includes 1,025 nebulae down to mag. 13.

The great condensation in and towards the Virgo region between galactic longitudes 250° and 270° and its prolongation beyond the north galactic pole has been known for many years, and the irregularities in the south galactic hemisphere are

also marked. The lack of extragalactic systems within 10° of the galactic equator in both hemispheres is well accounted for by the known existence of vast clouds of obscuring matter in the galaxy. This corresponds to the 'belt of avoidance', the limits of which have been investigated by Hubble over three quarters of the great circle. In some parts the limits of the 'belt of avoidance' approach within a few degrees of the great circle, and faint small nebulae have been photographed in these regions: in other longitudes the limits reach much farther away, and in some parts extend so far as 30° .

The evidence for the whole sky is therefore not complete by something like a fifth, although there is no reason to think that this missing fraction would seriously affect the results.

The distribution of some of the fainter and therefore presumably much more distant nebulae was investigated by Hubble in 1934 (*Mt. Wilson Cont.*, No. 485). He eliminated the brighter ones which are included in Shapley's catalogue, and the material consisted of about 44,000 nebulae distributed over three quarters of the sky north of -30° Dec. Almost all these are very faint, with a limiting magnitude of 20. A similar piece of work was undertaken about the same time from plates obtained by the Crossley reflector of 36 inches diameter, on which 15,000 small nebulae were counted up to mag. 19. In neither case was the south circumpolar region represented between -30° and -90° , and the plates examined covered only about 2 per cent of the total area available, each plate being taken as a sample of the distribution in that particular region, and covering presumably, in the case of the 100-inch reflector at Mt. Wilson, about a quarter of a square degree of good definition. At the Lick

Observatory, the scale of the 36-inch reflector plates was much smaller owing to the shorter focal length, and so covered about three times as much; here 489 plates were examined. The frequency curve of successive photographic magnitudes (Nm) was computed on the assumption that the numbers increased according to an equable distribution of the nebulae in space. Hubble found that the observed frequency curve of $\log Nm$ closely approximated a Gaussian error curve, which would agree with the assumption of equable distribution, if a reasonable dispersion in magnitudes with distance was allowed.

Bok in 1934 again investigated the question, using Hubble's observational material. He calculated the form of the frequency function for the number of systems per unit area of the sky, on the assumption that they are distributed at random. Hubble's observed frequency curve was then compared with the curve of calculated random distribution after ample allowance for dispersion in the limiting magnitudes had been made, and Bok came to the conclusion that this brings out very clearly that the distribution of the faint and distant systems is also not at random. He therefore agrees with Shapley that the general distribution is not homogeneous, and that the tendency to clustering is one of the chief characteristics of the extragalactic universe, so far as we have been able to plumb its depths.

There seems to be little doubt, therefore, that while the uniform distribution is a useful assumption of mathematical necessity, it is certainly not a 'fact of observation'. The evidence of the nearer systems within a radius of 4,000 kiloparsecs is directly contrary to the assumption, while beyond this limit the evidence is quite insufficient to arrive at a definite conclusion in its favour.

The Nutritive Value of Pasteurized Milk

MUCH controversy has arisen over the question whether the bulk of milk sold in Great Britain should be pasteurized or not. There is no doubt that many epidemics have been caused by the consumption of raw milk, which there is presumptive evidence would not have taken place if the infecting bacteria had been destroyed by pasteurization before the milk reached the consumer. On the other hand, experimental evidence has been brought forward to show that the nutritive value of milk is impaired by pasteurization, although in other experiments no significant change in nutritive value could be demonstrated.

The problem is that of producing a 'safe' milk at an economic price; up to the present, the average consumer has refused to pay the higher price of milk obtained from disease-free cows and produced under conditions reducing the risks of contamination to a minimum. However, even under the best conditions, there is always the risk of a worker suffering from an infectious disease contaminating the milk he is handling and so spreading the disease over a wide area, so that adequate heat treatment of the milk may prove the only safeguard, but this can only be recommended with confidence if the nutritive value is not impaired

by the heating process, or only impaired in a manner which can easily be remedied.

Towards the end of 1934, an informal conference was called by the Milk Marketing Board's Advisory Committee on Milk Publicity, at which representatives of Government Departments, the Medical Research Council and the Milk Marketing Boards were present: the object of the conference was to consider what further investigations were required on the nutritive value of milk. The conference entrusted the task of conducting these investigations to a special committee—the Milk Nutrition Committee—of which the first report, dealing with the results of work on rats and the direct chemical estimation of vitamin potency, has recently been published*. Investigations in schools and with calves will be reported in the near future.

The greater part of the work described in this report has been carried out by Dr. S. K. Kon and his colleagues at the National Institute for Research in Dairying, Shinfield, near Reading: the experiment on the availability of the calcium and phosphorus of pasteurized milk was duplicated at the Rowett Research Institute, Bucksburn, by Dr. D. W. Auchincloss. The same general plan was followed in all the experiments: the samples of raw milk were drawn from the tip tank of the pasteurizing plant after careful mixing, and those of the pasteurized milk were taken after cooling when about half the vat had been emptied. The pasteurization was carried out under commercial conditions by Messrs. Emerson and Chanin, Reading, or at the headquarters of the Aberdeen Milk Pool. The temperature of pasteurization was frequently checked and bacteriological and phosphatase tests were carried out on the milks; in addition, daily estimations of fat and total solids were made during part of the experimental period. The milks were compared as sources of calcium and phosphorus, protein and vitamin B in experiments on rats, and as sources of vitamin A and carotene and vitamin C by chemical tests. The results of these experiments can be quite briefly summarized: pasteurized milk is as good a nutritive agent as raw milk, except in the case of vitamin B₁ and vitamin C.

Since the results of these experiments are of considerable importance, it may be advisable to describe them in more detail, especially as the assessment of the value of the evidence adduced must depend ultimately on the investigators' attention to detail. For the determination of the availability of the calcium and phosphorus in the

milks, a complete metabolism experiment was carried out, Kon employing two dozen animals and Auchincloss a dozen. The animals were housed in metabolism cages, in which the excreta could be collected, and the feeding dishes were designed to prevent any scattering of the food. The rats were grouped in pairs according to sex and litter, and the amount of basal diet offered was slightly in excess of that consumed by the animal with the smaller appetite; one animal received raw milk and the other the same amount of pasteurized milk. The basal diet consisted of dried eggwhite, calcium- and phosphorus-free salt mixture, castor sugar, maize starch and butter fat, with supplements of cod liver oil and vitamin B₁ extract. The quantity of milk supplied daily was calculated to supply about 60 per cent and 70 per cent of the normal requirements of calcium and phosphorus respectively. The experiment was continued for five weeks: the deposition of calcium and phosphorus in the tissues of the animals was determined by two entirely independent methods. In the first, the retention was found from the total intake of these elements in the food and milk and the amounts excreted in the urine and faeces. In the second, the retention was estimated from the amounts present in the bodies of the animals at the end and at the beginning of the experiment; the latter figures were obtained by analyses of a similar number of litter mate controls of the same sex as the experimental animals, killed at the beginning of the experiment. For pooled figures the two methods agreed within 0.2 per cent in the case of calcium and 2.0 per cent in the case of phosphorus; the slight discrepancy in the case of phosphorus was probably caused by a small loss during ashing of the rats. The agreement between the two methods indicates that the metabolism experiment had been carried out satisfactorily.

It was found that the animals retained some 80 per cent of the ingested calcium and phosphorus, irrespective of the type of milk given. Statistical treatment of the results showed that pasteurization had no deleterious effects upon the availability of these elements. The only statistically significant differences were a retention by the does on pasteurized milk of 3 per cent more calcium than their litter mates on raw milk and a greater increase in weight of the bucks on raw milk. In all the rats, about 90 per cent of the calcium excreted was found in the urine and about 90 per cent of the phosphorus in the faeces; the reason for the high excretion of calcium in the urine, which is unusual, was not determined.

There was a similar failure to detect any difference between raw and pasteurized milk when the biological value and digestibility of the proteins and the total nutritive values of the milks

* Milk and Nutrition: New Experiments reported to the Milk Nutrition Committee. Part 1: The Effect of Commercial Pasteurization on the Nutritive Value of Milk, as determined by Laboratory Experiment. (From the National Institute for Research in Dairying (University of Reading) and the Rowett Research Institute, Bucksburn, Aberdeen.) Pp. 87. (Reading: National Institute for Research in Dairying, Shinfield, 1937.) 2s. 6d. net.

were compared in experiments on rats. In the latter experiments, the milk was the only food supplied, but was supplemented by the addition of small amounts of iron, copper and manganese: the manganese was shown to be an essential element for growth. Similar experiments on the value of the milks as sources of the vitamin B complex disclosed, however, that pasteurized milk was a significantly less satisfactory source than raw milk: the difference was, however, observed only in the case of the more rapidly growing bucks. The deficient diet used was supplemented by 8 ml. milk daily, an amount which was known to be sufficient for subnormal growth only. This difference between the milks was not seen when larger amounts were given daily, as in the experiments on their total nutritive value, or when the animals grew more slowly, as in the case of the does. The difference might, however, be disclosed during lactation, when the requirements for vitamin B are much greater.

The vitamin A and carotene contents of the milks were determined spectrophotometrically and by the tintometer, on butters churned from both types of milk over a period of five weeks. No destruction of vitamin A or carotene by pasteurization was found. The vitamin C content was determined chemically, by titration with the indophenol reagent, both before and after reduction of the milks with hydrogen sulphide: both the reduced and the reversibly oxidized forms of

ascorbic acid showed loss on pasteurization, the loss being greater in the case of the latter. The total loss was about 20 per cent. Milk taken directly from the udder without exposure to light contains only the reduced form of ascorbic acid and can be pasteurized without loss of the vitamin by the holder method, in the absence of copper: the reversibly oxidized form of ascorbic acid is formed by the action of light upon the milk and is affected by pasteurization.*

To sum up, pasteurized milk may contain less vitamin B (presumably B₁) and vitamin C than raw milk, but will in other respects have the same nutritive value. Where milk is not the sole diet, such losses will have no significance, provided the diet also contains cereals and fruit. Where milk is the sole diet, a supplement of fruit juice and a yeast extract or other rich source of vitamin B₁ should obviate any possibility of the diet being inadequate in these respects, although, with a proper intake, the lower content of pasteurized milk in vitamin B is unlikely to be detected and it is now usual to supplement the milk with fruit juice (together with vitamins A and D, in the form of cod liver oil or a concentrated preparation of these vitamins). These experiments suggest that there need be no fear of malnutrition from the universal use of pasteurized milk; admittedly the risk of infectious disease will be considerably reduced.

Bicentenary of Galvani

TEN years ago all Italy joined in honouring the memory of Volta on the centenary of his death; now arrangements are being made at Bologna to commemorate the bicentenary of the birth of his fellow countryman, Galvani, whose discoveries paved the way for those of Volta and led to the invention of the voltaic pile. Though the Galvani celebrations will not be on the same scale as those of ten years ago, they will help to recall the fundamental work done in Italy on current electricity which has had such fruitful results.

Aloisii Galvani was born in Bologna on September 9, 1737, and was thus about eight years older than Volta. After a youth in which theology and mysticism played a part, he settled down to the study of medicine, and in 1762, after writing a thesis "On the Bones, their Nature, and their Formation", was made a lecturer in the University of Bologna and reader in anatomy to the institute of the city. He was successful both as a teacher

and a surgeon and became known for his researches in comparative anatomy. It was as an anatomist and physiologist, and not as a physicist, that he made the experiments which have immortalized his name.

The work for which Galvani is remembered was done during the years 1780-91. At least as early as 1780, he began observing the effects on muscular contractions caused by the use of the electrical machine, the Leyden jar and Volta's electrophorus. In 1782 he drew up a paper entitled "On the Nervous Force and its Relation to Electricity". His experiments were made on frogs in particular. Assisted by his nephew, Camillo Galvani, in 1786 he began observations on partly dissected frogs which had been suspended by hooks from the iron rails of the balcony of his house. These he first described in a paper "Esperimenti circa l'Elettricità dei Metalli", and in a Latin dissertation of 62 pages dated October 30, 1786, afterwards to form the most important part

of his work of 1791. Galvani was in doubt as to how to explain the effects he observed, and, said J. D. Forbes, who had carefully studied his writings, "in the short space of a few weeks, he had abandoned his earlier notion of the metals being the source of the electricity, and ascribed the effects to the proper electricity of the nerves and muscles". Still pursuing his experiments at intervals, in 1791 he published his most famous, and now very rare, memoir, "De Viribus Electricitatis in Motu Musculari Commentarius", the appearance of which roused great interest in scientific circles.

The first German accounts of Galvani's views were published in 1792 by a young doctor, E. J. Schmuck, and in October of that year Volta wrote his two letters to Cavallo entitled, "Account of some Discoveries made by Mr. Galvani of Bologna, with Experiments and Observations on them". The letters were in French, the first sentence being, "Le sujet des découvertes et des recherches, dont je vais vous entretenir, Monsieur, est l'électricité animale". Volta had sent the letters to be read to the Royal Society as an acknowledgement of his election as a foreign member in 1791. They were read at a meeting of the Society on January 31, 1793, and were duly published in the *Philosophical Transactions*. In 1794, when Volta was awarded the Copley Medal, Sir Joseph Banks in his address said:

"The experiments of Professor Galvani, until commented upon by Professor Volta, had too much astonished, and, perhaps, in some degree, perplexed many of the learned in various parts of Europe. To Professor Volta was reserved the merit of bringing his countryman's experiments to the test of sound reasoning and accurate investigation. He has explained them to Dr. Galvani himself and to the whole of Europe, with

infinite acuteness of judgment and solidity of argument; and through the medium of the *Philosophical Transactions* he has taught us that the various phenomena which presented themselves under the modifications of Dr. Galvani's experiments hitherto tried, are wholly owing to the excessive irritability of the nerves when subjected to the action of portions of the electric fluid, too minute to be discovered, even by the delicate electrometer of our ingenious brother, Mr. Bennet, of Worsworth; and he has detected in the metals, which Dr. Galvani considered as mere agents in conducting his animal electricity, that very existing principle which the Doctor and his followers had overlooked."

Forbes considered the award of the Copley Medal to Volta, rather than to Galvani, a questionable decision, for "the great value of Volta's paper, at the time, was undoubtedly that it directed the attention of English experimenters to Galvani's discoveries, then quite recent and probably imperfectly known". That Galvani was little known and had not travelled, while Volta was personally known in both Paris and London, may have had something to do with the decision.

From 1791 onwards, Galvani did little more to add to his fame. His wife died, his health declined, and when after the French Revolution the Cisalpine Republic was set up, he declined to take the oath of allegiance to the new authorities and was dismissed from his offices. He died on December 4, 1798, apparently at the house of a brother to which he had retired after his dismissal. His writings were republished in one volume in 1841 by the Academy of Sciences of Bologna.

As regards the oft-repeated story of Galvani's observations on frogs being connected with the preparation of a dish for his invalid wife, Forbes dismisses it as an absurd invention.

Obituary Notices

Prof. D. Morgan Lewis

DAVID MORGAN LEWIS, emeritus professor of physics in the University of Wales, died at Aberystwyth on July 28, aged eighty-five years.

Born at Eglwyswrrw, Pembrokeshire, in 1851, he was the eldest son of the Rev. Evan Lewis, minister of the Welsh Independent Church at Brynberian and a prominent figure in his denomination. His early education was received at a local British school and at Cardigan, and later he entered the Presbyterian College, Carmarthen, to train for the ministry. Here he became proficient in mathematics and in 1873 entered Trinity College, Cambridge, where he was

20th Wrangler in 1877. Afterwards he studied physics at the Cavendish Laboratory.

In 1878 Lewis was ordained as minister of the English Congregational Church at Hirwaun, Glam., where he served until 1883. The advent of the new Welsh national colleges decided him to seek a wider field and in the latter year he resigned his pastorate and returned to work at the Cavendish Laboratory. In 1884 he was appointed as assistant to Andrew Gray, professor of physics in the new University College of North Wales at Bangor, with whom he worked in full accord until 1891, when he was appointed to the professorship at Aberystwyth in

succession to D. E. Jones. Here he worked quietly, and gradually built up an efficient department of physics until his retirement in 1919. He was married in 1894 to Miss Annie Powell of Carreg Cennen, Carmar., who predeceased him in 1932.

Prof. Lewis was of a modest and retiring disposition, and greatly disliked publicity. Yet he could be very enthusiastic in those causes which, in his opinion, mattered. While at Hirwain he inaugurated and lectured to classes under the Science and Art Department, and later wrote considerably to the Welsh local Press to stress the importance of scientific and technical education in the new secondary schools which were then being established. He served the University Colleges of Bangor and Aberystwyth and the University of Wales well during their formative years, and the cause of adult education in the Principality found in him a willing helper. During many years, he served as a governor of Aberystwyth County School and was for a period chairman.

After his retirement, Lewis's main interests were in the affairs of his religious denomination, in Welsh hymnology and in archaeology. Until quite recently, his quiet, dignified figure could always be seen at the meetings of the British Association, among whose members he had a host of friends.

T. C. J.

DR. PEMBOY PHILLIPS, director of the Hydrological Service of the Physical Department, Egyptian Ministry of Public Works, died in Cairo on August 4,

at the age of fifty-seven years. Previous to the Great War, he was a lecturer in physics in the University of London and during the War had a commission in the Sound-Ranging Section of the Royal Engineers, with which he saw service in France and Palestine. He joined the Egyptian Government Service in 1919, and was responsible for the collection and discussion of statistics relating to the water supply of the Nile. He did valuable work in the study of the hydrology of the Nile Basin and in the preparation of the large irrigation projects on the Nile.

We regret to announce the following deaths:

Dr. G. P. Clinton, formerly botanist of the Connecticut Agricultural Experiment Station, known for his work in mycology, on August 13, aged seventy-one years.

Prof. F. B. Loomis, professor of geology in Amherst College, Mass., an authority on vertebrate paleontology, on July 24, aged sixty-three years.

Mr. Andrew Mellon, founder of the Mellon Institute of Industrial Research at Pittsburgh, Pa., sometime American Ambassador in Great Britain, on August 26, aged eighty-two years.

Prof. Luigi Pernier, professor of archaeology and the history of ancient art in the University of Florence.

Lord Rothschild, F.R.S., a trustee of the British Museum and founder of the Tring Zoological Museum, on August 27, aged sixty-nine years.

News and Views

Sir Thomas Grainger Stewart (1837-1900)

SIR THOMAS GRAINGER STEWART, the eminent Scotch physician, who died on February 3, 1900, was born at Edinburgh on September 3, 1837. He qualified in 1858, and then visited the medical centres on the Continent, where he came in contact with Virchow, Schönlein and Traube in Berlin, and Oppolzer, Skoda and Hebra in Vienna. On his return to Edinburgh, he was made physician to the university wards in the Royal Infirmary. In 1876 he was appointed professor of physics and proved an exceptionally gifted teacher. He was one of the first in Great Britain to direct attention to the deep reflexes, and under the title of "Paralysis of the Hands and Feet from Diseases of the Nerves", he first described the condition known as multiple neuritis. For many years he held a foremost position as a consultant throughout Scotland and the north of England. His chief publications were "A Practical Treatise on Bright's Diseases of the Kidneys" (1868), "The Teaching of Medicine in Edinburgh" (1877) and "An Introduction to Diseases of the Nervous System" (1884). He was the recipient of many honours. In 1882 he was appointed physician to the Queen in Scotland, in 1887 he was made M.D. *honoris*

causa of the Royal University of Ireland, in 1890 he was elected president of the Royal College of Physicians of Edinburgh and honorary fellow of the College of Physicians of Philadelphia, in 1894 he was knighted, and in 1898 he was elected president of the British Medical Association when the annual meeting was held in Edinburgh.

Samuel Siegfried Karl von Basch (1837-1905)

THIS eminent Austrian physiologist and physician was born on September 9, 1837, at Prague. After studying medicine in his native town and Vienna, he qualified in 1862 in Vienna, where he acted as assistant for several years to Dittel, Jaeger, Turk and Kalisko. In 1865 he went to Mexico, where he was appointed Court physician to the Emperor Maximilian, who was shot on June 19, 1867, and himself narrowly escaped execution. After his return to Vienna he carried out some important experiments on the action of nicotine on the movements of the intestine, and in 1878 was appointed extraordinary professor in experimental pathology. He was the author of numerous publications, but his chief work was "The Physiology and Pathology of the Circulation" (1892), which he dedicated to his former teacher, the celebrated physio-

logist Karl Ludwig. Basch is best known for his invention of a sphygmomanometer, by which he inaugurated the clinical measurement of the blood pressure. He also did valuable work on pulmonary oedema, cardiac dyspnoea and the innervation of the uterus. His death took place on April 25, 1905.

Local Government in Roman Britain

A DOCUMENT of importance in its bearing on the organization of local government in Roman Britain has been brought to light in the course of the fifth season's excavation on the site of the Roman town of Brough, which has just closed. The investigation of this site, which is situated on the north bank of the Humber, commanding the crossing of the river by the Lincoln-York road, is being carried out by the Brough Excavation Committee under the direction of Mr. Philip Corder and the Rev. T. Romans. The present season's work has been directed to laying bare one of the four towers of rectangular form, twenty-five feet wide by ten feet deep, which were added to the front wall of fortification, possibly early in the fourth century. The most important find of the season was an inscribed slab, 2 ft. 3 in. high by, originally, about four feet long (*The Times*, August 27). Mr. Eric Birley reports on the inscription that it commemorates the provision of a stage at his own expense by Marcus Ulpius Ianuarius, *Aedile* of the village of Petuaria, in honour of the Imperial family of Antoninus Pius (A.D. 138-161) and of the spirits of the deified emperors. This inscription confirms the name Petuaria, and is one of the few known instances of the epigraphic confirmation of Romano-British names.

FURTHER, and more important, the inscription affords evidence of a step in the development of the unit of local governments in Britain from the tribal area, here that of the Parisii, to the self-governing canton with its seat of government at the old tribal capital, or a newly erected town. Although such tribal cantons were known from inscriptions at Caerwent and Wroxeter, this is the first mention of a tribal magistrate in Britain. Furthermore, being denominated as the *Aedile* not of the tribal area, as in the previously known inscriptions, but of Petuaria itself, this indicates, in the interpretation of Mr. Birley, a further stage of development in which the central town with its college of four regular magistrates, two *duovirs* and two *Aediles*, was gaining in importance at the expense of the tribal organization. This inscription is also the first epigraphic evidence of the practice in Britain of a magistrate conferring benefactions in return for the honour of election to office.

Arctic Weather Reports

ONLY forty-one years have passed since Nansen made his perilous and unsuccessful attempt to drift with the arctic ice from northern Siberia across the North Pole to the neighbourhood of Greenland, yet since July at least one London morning newspaper has been publishing daily a weather report from the region of the North Pole along with similar reports

from New York and various Continental capitals. Such observations are not at present of great importance to weather forecasters, because the normal travel of weather systems generally tends to be circumpolar, and, moreover, the gap between the Pole and other arctic weather stations—even Spitzbergen—is a very wide one, so wide that it is impracticable to complete a system of isobars to cover the polar regions. But as a landmark in the gradual spreading of a network of observing stations over the whole world, this event is important. Owing to the drift of the ice, a permanent station at the North Pole is impracticable, but the Russian station from which the published observations have been received has apparently not drifted very far from the Pole yet. Its co-ordinates at the end of August were about lat. 87° N., long. 2° E. The reports include an observation of the direction of the wind, and owing to the fact that these are not made exactly at the Pole, the direction can be given in the ordinary manner. At the Pole itself, of course, all winds are from the south, and direction would presumably have to be given in terms of longitude instead of being referred to the points of the compass.

Problems of Conquering Everest

THE problem of reaching the summit of Mount Everest is discussed in a paper in the *Himalayan Journal*, 9, and takes the form of a memorandum prepared by the Eastern Section of the Himalayan Club, with some comments on the conclusions by Mr. E. Shipton. Two main suggestions are made in the light of past experience. The first is that expeditions have been foredoomed to failure because they have attempted to climb the north ridge too quickly. It is contended that men who have stood the strain of reaching the North Col cannot hope to do the remaining 6,300 feet in three days. The writers quote much evidence in favour of their statement, but Mr. Shipton is equally sure that above 23,000 feet a man deteriorates in muscle and energy quickly, and therefore delay at and above that height must be avoided. The second suggestion is that instead of trying in May and June when the effort is a race with the approaching monsoon, it would be better to make the attempt after the monsoon, in October or even in April. Days in October are certainly shorter than in May, but wind velocities so far as is known are slightly lower. Mr. Shipton admits that post-monsoon conditions should be studied, but prefers the pre-monsoon season. Major K. Mason points out that one obvious drawback to October is that it is a month of increasing wind, while May is a month of west winds decreasing owing to advancing monsoon currents.

The British Grid System

IN a paper on the British Grid system by Johnstone Wright, the engineer of the Central Electricity Board, presented to the Engineering Institute of Canada, at Montreal in June last, an interesting account is given of the development of the Grid system in

The History of Evolutionary Thought as Recorded in Meetings of the British Association*

By Sir Edward B. Poulton, F.R.S.

President of the British Association

SIR WILLIAM THOMSON, in his address at Edinburgh in 1871, said that "the real origin of the British Association" was given in the words of a letter written by David Brewster to John Phillips on February 23, 1831, a few months before the first meeting: "The principal object of the Society would be to make the cultivators of science acquainted with each other, to stimulate one another to new exertions, and to bring the objects of science more before the public eye, and to take measures for advancing its interests and accelerating its progress". That the time was fully ripe for the birth of the Association is made very clear by the words written by John Keble to a friend, referring to the D.C.L. degrees conferred, at the Oxford meeting in 1832, on David Brewster, Robert Brown, John Dalton and Michael Faraday: "The Oxford Doctors have truckled sadly to the spirit of the times in receiving the hodge-podge of philosophers as they did"—an opinion on which Lord Salisbury commented at the Oxford meeting in 1894: "It is amusing at this distance of time, to note the names of the hodge-podge of philosophers whose academical distinctions so sorely vexed Mr. Keble's gentle spirit". It is not only amusing but also pathetic that such words should have been used by a revered member of a University which had done splendid service for science,

as has been so well shown in Dr. R. T. Gunther's volumes¹.

Faced by the serious duty of preparing this address, I felt that the best hope of interesting you would be to choose a subject which has received special attention at our meetings. I have selected the progress of thought on organic evolution as it may be followed in addresses, papers, and discussions, mainly restricting myself to the series of meetings which began with the jubilee at York in 1881, the first of many that I have had the pleasure of attending.

The British Association provides a very favourable field for the discussion of many-sided subjects such as evolution—subjects which attract members from very different, as well as from closely related, sections. Hence a wide range of varied experience is open to one who can look back over more than half a century; and I do not propose to exclude some of the humorous sayings and incidents which, from time to time, have enlivened our meetings and contributed to their success. Some of them certainly deserve to be rescued from oblivion, although to perform this pious duty I must risk the enmity of the Goddess of Folly, who as Erasmus tells us, proclaimed: "I hate a man who remembers what he hears".

The fiftieth anniversary at York was a memorable meeting, with Sir John Lubbock (Lord

* PRESIDENTIAL ADDRESS DELIVERED AT NOTTINGHAM ON SEPTEMBER 1.

Avebury) as president, and the chair of every section except economics, under Grant Duff, taken by a past-president of the Association.

I then enjoyed to the full one of the chief benefits conferred by our Association upon its younger members—the opportunity of meeting older men, up to that time only known to them by the fame of their discoveries. Prof. O. C. Marsh had come over from Yale, his main object being to buy for his University Museum the second and more perfect fossil of the wonderful ancestral bird *Archæopteryx*, with teeth and a long, lizard-like tail—clear evidence of reptilian origin. The earlier example had been bought for the British Museum at a price which was said to have provided the dowry for a professor's daughter, and Marsh soon realized, as he told me, that the second was not for sale on any terms. "We let the other go and I believe they would kill me if this were sold" was the reply given to him by the authority in Munich. He was, however, able to study the fossil, and his description and drawings of the teeth, in the Geological Section, followed the only attack on evolution itself, as distinct from its causes, which I have ever witnessed at any of our meetings. It was the exhibition by H. G. Seeley of his reconstruction of *Archæopteryx* from this fossil, which aroused the fury of the palæontologist, old Dr. Thomas Wright of Cheltenham: "Archæopteryx hasn't got a head, how can it possibly have teeth?" he growled, knowing nothing of the latest find or of the fact that a detached head and scattered teeth had been detected on the slab in which the older specimen was embedded. In spite of Prof. Newton's positive statement and the form of the teeth, drawn by Prof. Marsh at the request of the chairman, Dr. Wright, quite unconvinced, continued muttering "Archæopteryx is a very good bird", its virtue in his opinion entirely uncontaminated by any taint of reptilian affinity.

Prof. Marsh also read a paper in the Zoological Section on his own wonderful discoveries of toothed birds from the rocks of the western United States. Richard Owen, president of the Section, was in the chair and, with the memory of old and embittered controversies in his mind, the author told me that he had felt rather anxious in bringing this communication forward. But in that friendly atmosphere there was no reason for alarm. Owen welcomed the paper warmly and in confirmation told us, in the most charming manner, of the traces of teeth found in an embryo parrot.

FOSSILS AS EVIDENCE OF EVOLUTION

The event which stands out most clearly in my memories of the jubilee meeting is Huxley's evening lecture on "The Rise and Progress of Palæontology"—the science which provides an essential part of the foundation on which geographical, geological and biological evolutionary history has been built. The insuperable difficulty felt by the older naturalists was to believe that the land had been for the most part deposited under the sea, and to account for the presence of fossils, or as they were called, 'formed stones'. The true solution, Huxley explained, was found and published in 1669 by Nicholas Steno, a Danish professor of anatomy at Florence, who carefully studied certain fossils, known as 'glossopetræ', which abounded in the Tuscan rocks and were believed to be fossil fig-leaves. Steno, who was not satisfied with this interpretation, dissected a shark's head and showed that the 'glossopetræ' exactly corresponded in every particular with the teeth—"that in fact they were shark's teeth". The emphasis with which Huxley made this statement comes back to me after the lapse of nearly sixty years. From this, Steno was led to conclude that they were the teeth of shark-like fishes living in the Tuscan Sea and later embedded, with other remains, in the strata which had there accumulated.

I have not noticed the fanciful suggestion of "fossil fig-leaves" in any published version or account of Huxley's lecture that I have seen, but he certainly told us of it and it is an interesting example of the attempts made by the naturalists of the day to explain the fossils embedded in rocks then believed to be of terrestrial origin. I cannot resist the temptation of quoting Plot's* more ingenious and amusing effort to account for the well-known layer of oyster-shells (*Ostrea bellerophon*) found "... at some places here in England, particularly at *Cats-grove* [now *Katesgrove*] near Reading . . . ; which how they should come here without a *Deluge*, seems a difficulty to most men not easily avoided".

Plot was, however, helped "to a salvo" for his own objection by remembering that Reading was "a *Town* of very great *action* during the *Invasions* of the *Danes*, who cutting a deep trench cross between the *Kennet* and *Thames*, and inclosing themselves as it were in an *Island*, held it against King *Ethelred*, and *Alfred* his Brother a considerable time; from whence in all probability, the

Saxons having removed their *Cattle* and other provisions before the *Danes* arrival, 'tis likely that they might be supplied from their *Navy* with *Oysters*, which during the time of the abode of the *Army* on Land, might be a very suitable employment for it: Which conjecture, if allowed, there is nothing more required to make out the possibility of the bed of *Oysters* coming thither without a *Deluge*, but that *Cats-grove* was the place appointed for the *Armies* repast".

The probability of this suggestion may be inferred from the age of the 'Woolwich and Reading' beds in which the oysters are found—estimated by Prof. W. W. Watts and Prof. H. L. Hawkins at about 50–60 million years.

Dr. Plot's explanation of fossils in general, as well as of flowers, was of a very different kind. To account for their existence he appealed to "the wisdom and goodness of the *Supreme Nature*, by the *School-men* called *Naturans*, that governs and directs the *Natura naturata* here below, to beautify the World with these varieties; which I take to be the end of such productions as well as of most *Flowers*, such as *Tulips*, *Anemones*, &c. of which we know as little use as of formed stones".

The modest and withal amusing paragraph which follows I venture to quote in full as an example to be followed in scientific controversy:

"And thus I have given the grounds of my present *opinion*, which has not been taken up out of *humor* or *contradiction*, with intent only to affront other worthy Authors modest conjectures, but rather friendly to *excite them*, or any *others*, to endeavor collections of *shell-fish*, and parts of other *Animals*, that may answer such *formed stones* as are here already, or may hereafter be produced: Which when ever I find done, and the reasons alleged *solidly* answered, I shall be ready with acknowledgment to retract my *opinion*, which I am not so in love with, but for the sake of *Truth* I can cheerfully cast off without the least reluctance".

One chief object which, as I believe, Huxley had before him was to bring forward a calm, clear statement of the evidence on which alone it was possible to achieve that "reconstruction of an extinct animal from a tooth or bone", which had made so deep an impression on the imagination. The reconstruction was in fact a simple inference based on anatomical experience such as that gained by Steno when he dissected the shark and concluded that the 'glossopetræ' were the teeth of shark-like fishes. But this reasoning—that a fossil

tooth or bone on the surface of a rock, cannot by itself enable the geologist to predict that a skeleton of a certain type lies hidden beneath—seeming to diminish the glory of Cuvier's splendid work, was resented by Owen, who had replied with the bitter taunt that a tooth can tell us a great deal—a donkey can kick his master but he cannot eat him. This may have been the encounter referred to by Huxley when he wrote of a friendly meeting with Owen at the Zoological Section of the Association in Leeds (1858): "so that the people who had come in hopes of a row were (as I intended they should be) disappointed". In the same spirit, I think, Huxley was glad to speak of the 'glossopetræ' at the jubilee meeting, where Owen was president of a section, and calmly and simply, to reaffirm conclusions which are unassailable.

Huxley then passed on to Steno's further study of fossils and his proof of their relationship to terrestrial freshwater and marine organisms, and to his application of this evidence to the past condition of Tuscany—all discussed "in a manner worthy of a modern geologist" and later extended by Buffon to all parts of the world then known to be fossiliferous. These conclusions, "which almost constitute the framework of palæontology", only required one addition, made towards the end of the eighteenth century by William Smith, who showed that geological strata contained characteristic fossils so that rocks of the same age could be identified in all parts of the world, while the biologist could follow the changes in the living population of the globe—a record of constant extinction and continual generation of new species. We were then led to three general conclusions: (1) the vast length of time during which life has existed on the earth—"certainly for millions of years"; (2) the continual changes which living forms have undergone during this period; (3) the successive changes in the best-known fossil groups are such as we should expect if each series "had been produced by the gradual modification of the earliest form. . . ." This last conclusion meant evolution which so completely accorded with recent discoveries that "if it had not existed, the palæontologist would have had to invent it".

I can never forget the words spoken to me after the lecture by a dear friend of my youth, the late Viriamu Jones, Principal of University College, Cardiff: "At every sentence I felt myself bowing to Huxley and saying 'you are the greatest man here; no one else could have said that as you have said it'".

AGE OF THE EARTH

As Huxley's lecture continued in a calm spirit an embittered controversy, so his thoughts on the immensity of past geological and biological time lead naturally to another controversy on the age of the earth conducted intermittently at our meetings between 1892 and 1921. It is, I think, a good example of the invaluable help which the British Association brings to discussion when there appears to be a difficulty in reconciling the conclusions reached by the followers of different sciences. Lord Kelvin's estimate of a hundred million years as the period during which the earth had been cool enough to permit the existence of life upon its surface—a period reduced by Prof. Tait to ten million—was a great difficulty to geologists and biologists, who believed that an immensely longer time was required for the history of the fossiliferous rocks and the evolution of animals and plants. Thus, to quote only one instance, Darwin writing to Wallace in 1871 and referring to 'missing links', said, "I should rely much on pre-Silurian time; but then comes Sir William Thomson, like an odious spectre". The geologists resisted more firmly. Thus Sir Archibald Geikie, in his presidential address at Edinburgh in 1892, concluded his discussion of the subject with these words: "The geological record furnishes a mass of evidence which no arguments drawn from other departments of Nature can explain away, and which, it seems to me, cannot be satisfactorily interpreted save with an allowance of time much beyond the narrow limits which recent physical speculation would concede".

At the Leeds meeting in 1890 I had many opportunities of meeting Prof. John Perry, and when we were walking together on the Sunday afternoon, I asked him to tell me something of the Kelvin-Tait conclusions and how far they must be accepted. He had been a demonstrator under Kelvin and spoke of the intense interest with which he had followed his lectures at Glasgow, and he gave me no hope of escape. His change of opinion, throwing a most interesting light upon the influence of the British Association, was the result of the presidential address at Oxford in 1894, when Lord Salisbury chaffed the believers in natural selection, telling them that he did not wonder that they required many hundred million years for so slow a process, but that "if the mathematicians are right, the biologists cannot have what they demand. . . . The jelly-fish would have

been dissipated in steam long before he had had a chance of displaying the advantageous variation which was to make him the ancestor of the human race".

When Perry read this pronouncement, sweeping aside the firm convictions of biologists and geologists, he was led to re-examine the evidence and soon found a flaw. The heat of the earth had been calculated on the assumption of a conductivity uniform through the whole mass, but Perry showed that, with a conductivity becoming higher with increasing depth, the Kelvin-Tait estimate of the time required for cooling to the existing temperature—on which the age of the habitable earth had been based—must be immensely lengthened. Perry told me of this destructive criticism and very kindly helped me to make use of it in the address to Section D at Liverpool in which I replied to Lord Salisbury's amusing attack on the evolutionists.

Lord Lister was our president at Liverpool in 1896, and I cannot resist the temptation to digress for a moment and recall the address in which one of the greatest benefactors of mankind told us, with the utmost simplicity and modesty, the story of his life's work and the success which, in spite of all opposition, had been achieved. To hear him was an enduring inspiration.

The year 1896 was also the jubilee of Lord Kelvin's wonderful half-century of achievement in research and teaching, and I could not help feeling some regret that any criticism of his work should appear at this particular time. But in the kindly spirit of our Association such doubts were quite unnecessary. I well remember how he came one day to our sectional committee-room to bring me some volumes of his works, and how, as I have recorded before, in the following year as we were travelling across Canada after the Toronto meeting and the chance of collecting insects for a few minutes at each station could not be resisted, Lord Kelvin said to his wife, "My dear, I think we must forgive Poulton for thinking that the earth is so very old when he works so hard in one day out of all the endless millions of years in which he believes!"

The one line of evidence which left some anxiety in 1896 was suggested by Helmholtz, who allowed the sun only eighteen million years to have been giving out radiant heat at the present rate—a period Lord Kelvin was willing to extend to 500 million—and this estimated maximum was also accepted by Sir George Darwin, who, in his

address¹ at Cape Town in 1905, spoke of the new evidence obtained by M. and Mme. Curie in their proof that radium gives out heat, and quoting in confirmation the work of R. J. Strutt, W. E. Wilson and G. H. Darwin, finally concluded that "the physical argument is not susceptible of a greater degree of certainty than that of the geologists, and the scale of geological time remains in great measure unknown". The light thrown by radium upon the Helmholtz estimate was also referred to in the presidential address of Ray Lankester at York in 1906, of J. J. Thomson, quoting the work of Strutt, Joly and Rutherford, at Winnipeg in 1909, and became a predominant subject in the joint discussion on the age of the earth, between Sections A, C, D and K, at Edinburgh in 1921². Lord Rayleigh, in opening this discussion, concluded "that radioactive methods of estimation indicate a moderate multiple of 1,000 million years as the possible and probable duration of the earth's crust as suitable for the habitation of living beings. . . ."

Geologists and biologists do not profess to know the age of the earth as the abode of life, but they are sure that, in the words used by Sir William Turner at Bradford in 1900, its birth "must have been in the far-distant past, at a period so remote from the present that the mind fails to grasp the duration of the interval".

ORGANIC EVOLUTION

I fear that too much of our time has been occupied by the attempt to show that the field is clear for the discussion of organic evolution, but until this could be done any such discussion appeared to be wellnigh useless.

It is, I think, a mistake to emphasize too strongly the very natural shock received by many who read the "Origin" or heard of its teaching for the first time and without any preparation; and I believe an even greater mistake to criticize the clergy for the time that elapsed before their acceptance of the new teaching. I shall never forget the reception of Aubrey Moore's paper, "Recent Advances in Natural Science in their Relation to the Christian Faith", by the Church Congress at Reading in 1883³. No speaker could have carried his audience with him more thoroughly: there was not a single protest or indication of dissent—nothing but enthusiastic applause. The Bishop of Oxford, Dr. Mackarness, was in the chair when the paper received this unanimous welcome—

only twenty-three years after the Oxford meeting at which another Bishop of Oxford put his rude and foolish question to Huxley. It is pleasant to know that their celebrated encounter left no bitterness, for Huxley wrote in 1891 to Francis Darwin—"In justice to the Bishop, I am bound to say that he bore no malice, but was always courtesy itself when we occasionally met in after years".

I remember as a youth receiving a gentle parental warning against committing myself too entirely to a belief in evolution—a very different experience from that of our president at Hull in 1922, Sir Charles Sherrington, who in 1873 was persuaded by his mother to take the "Origin" with him on his summer holiday, with the inspiring words—"It sets the door of the Universe ajar!"

I have already recalled Dr. Wright's indignation at York in 1881 as my only experience of opposition to a belief in organic evolution at any of our meetings, and the published proceedings confirm this impression of unanimity. Thus, R. H. Traquair, addressing the biologists at Bradford in 1900, said, "I hardly think that we should now find a single scientific worker who continues to hold on to the old special creation idea"; and Lord Salisbury at Oxford in 1894, referring to Darwin, said, "He has, as a matter of fact, disposed of the doctrine of the immutability of species. It has been mainly associated in recent days with the honoured name of Agassiz, but with him has disappeared the last defender of it who could claim the attention of the world". The mention of this great American naturalist recalls Tyndall's fine address at Belfast in 1874 and his memories of Agassiz's words, "I was not prepared to see this theory received as it has been by the best intellects of our time. Its success is greater than I could have thought possible".

Huxley, who had seconded the vote of thanks to Lord Salisbury, wrote to Hooker a few days later: "It was very queer to sit there and hear the doctrines you and I were damned for advocating thirty-four years ago at Oxford, enunciated as matters of course—disputed by no reasonable man!—in the Sheldonian Theatre by the Chancellor. . . ."

A letter written two days earlier to Boyd Dawkins records Huxley's opinion of another part of the address. "Lord Salisbury gave himself away wonderfully, but he was so good about Darwin himself that I shut my eyes to all the nonsense he talked about Natural Selection".

MOTIVE CAUSES OF ORGANIC EVOLUTION

Leaving now the subject of organic evolution itself, as generally accepted, I wish to speak on the difficult question of its motive causes which for many years have formed the subject of addresses, discussions and papers at our meetings. The great division into two opposed theories of causation became clear in 1887, when Weismann attended the meeting at Manchester, and a discussion on "The Hereditary Transmission of Acquired Characters" was held in Section D. From that time, evolutionists attending our meetings have been either 'Lamarckians', following Erasmus Darwin, Lamarck, Buffon and Herbert Spencer, or 'Darwinians' who followed Darwin and Wallace. Darwin himself, however, included the Lamarckian conception of 'use-inheritance' as a motive cause, although believing it to be far less important than natural selection. The term 'Neo-Darwinian' has therefore been applied to those who, accepting Weismann's teaching, reject 'use-inheritance' altogether.

It must always be remembered that, apart from any theory of causes, the world owes its belief in organic evolution to all the great men whose researches and teaching have founded the two schools, and perhaps chiefly, at any rate, among the English-speaking nations, to Herbert Spencer. I was first led to realize the extent of his trans-Atlantic popularity when I learned from an American story greatly enjoyed in those far-off undergraduate days, that his books were keenly appreciated by a bashful hero, who was so far from sharing the sublime confidence of their author, that he was only led to perform the most fateful action in life by the pressing advice of a very young nephew who assured him, in the presence of the lady, that if he was fond of her, the proper thing to do was to kiss her. Herbert Spencer's infallibility certainly lent itself to such stories as that of his supposed reply to an argument—"That can't be true, for otherwise 'First Principles' would have to be re-written—and the edition is stereotyped"; or how Darwin said that to read Spencer always made him feel like a worm, but that he retained the worm's privilege of wriggling, and at another time "wonderfully clever, and I dare say mostly true". But, allowing for a style which provoked these and other amusing comments, we must never forget that believers in the doctrine of organic evolution owe an immeasurable debt to Herbert Spencer.

James Russell Lowell's amusing lines in the "Biglow Papers"¹⁸ appear to prove that Lamarckism was prevalent in America many years before the "Origin":

"Some flossifers think that a fakkilty's granted
The minnit its proved to be thoroughly wanted,

Ez, fer instance, thet rubber-trees fust begun
bearin'

Wen p'litikkle conahuncoes come into wearin',—
Thet the fears of a monkey, whose holt chanced
to fail,

Drowed the vertibry out to a prehensile tail".

The year of the Manchester meeting, 1887, was the fiftieth anniversary, and we are now celebrating the centenary, of the entry in Darwin's pocket-book:

"In July opened first note-book on Transmutation of Species. Had been greatly struck from about the month of previous March on character of South American fossils, and species on Galapagos Archipelago. These facts (especially latter), origin of all my views".

It is especially interesting to recall that these views, as Prof. Newton told us in his address to Section D, the biological section, did not include natural selection, which only came into Darwin's mind when he read Malthus, "On Population", in October 1838. Newton, who had read the proof-sheets of the great "Life of Darwin", published later in 1887, then spoke of Wallace's independent discovery, made twenty years after Darwin's, a discovery suggested to him also by reflecting on Malthus, and of the friendship between the two great men to whom this fruitful conception had come, referring the cynic who would "point the finger of scorn at the petty quarrels in which naturalists unfortunately at times engage" to this "greatest of all cases, where scientific rivalry not only did not interfere with, but even strengthened, the good-feeling which existed between two of the most original investigators". Here I cannot resist the desire to quote a part of the speech made by Wallace at the most thrilling scientific gathering I have ever attended—the fiftieth anniversary of the Darwin-Wallace essay read before the Linnean Society on July 1, 1858, only twelve days after the arrival of Wallace's letter and manuscript from the Moluccas. Wallace then said, on July 1, 1908:

"The idea came to me, as it had come to Darwin, in a sudden flash of insight: it was thought out in a few hours . . . and sent off to Darwin—all

within one week. I was then (as often since) the 'young man in a hurry': he, the painstaking and patient student, seeking ever the full demonstration of the truth that he had discovered, rather than to achieve immediate personal fame. . . . If the persuasion of his friends had prevailed with him, and he had published his theory, after ten years'—fifteen years'—or even eighteen years' elaboration of it—I should have had no part in it whatever, and he would have been at once recognized, and should be ever recognized, as the sole and undisputed discoverer and patient investigator of the great law of 'Natural Selection', in all its far-reaching consequences"¹¹.

Amusing evidence of the difficulty with which this "great law" was understood is afforded by a verse written by Lord Neaves and dated May 1861:

"A deer with a neck that was longer by half
Than the rest of its family's (try not to laugh),
By stretching and stretching, became a Giraffe,
Which nobody can deny"¹².

Yet Wallace, referring to Lamarck's hypothesis and "that now advanced", had written in his section of the joint essay:-

"Neither did the giraffe acquire its long neck by desiring to reach the foliage of the more lofty shrubs, and constantly stretching its neck for the purpose, but because any varieties which occurred among its antitypes with a longer neck than usual at once secured a fresh range of pasture over the same ground as their shorter-necked companions, and on the first scarcity of food were thereby enabled to outlive them".

There were fortunately others who did not launch such ill-aimed criticism. Thus Prof. Newton, reminding the Section that the new teachings had been at once accepted by Canon Tristram¹³ before the appearance of the "Origin of Species" (on November 24, 1859), expressed, with all the enthusiasm of one who was devoted to the same delightful branch of natural history, "the hope that the study of ornithology may be said to have been lifted above its fellows". It was indeed very fortunate that the Darwin-Wallace essay should have been read so soon after its appearance by a naturalist who looked on the species question as did Tristram—a great traveller and observer who studied indefatigably the birds he loved, as living creatures and in as many countries as he could visit.

At the last meeting of the British Association in Nottingham (1893), Canon Tristram was president of Section D and, in his address, gave an account of the observations referred to by Newton at Manchester. The historic interest of this early acceptance of natural selection is such that I have prepared a brief abstract of his chief conclusions:

During a visit of many months to the Algerian Sahara in 1857-58, he "noticed the remarkable variations in different groups, according to elevation from the sea, and the difference of soil and vegetation". On his return he read the Darwin-Wallace essay and wrote, "It is hardly possible, I should think, to illustrate this theory better than by the larks and chats of North Africa". He then explained how the colours arose by selective destruction of birds which harmonized less well than others with the surface of the desert; and similarly with other larks having "differences, not only of colour, but of structure", chiefly "marked in the form of the bill": He took as examples a very long-billed lark (*Galerita arenicola*), resorting exclusively to the deep, loose, sandy tracts, and a very short-billed allied species (*G. isabellina*), haunting the hard and rocky districts. He then pointed out that there is individual variation in the bills of larks and that the shorter-billed birds would be at a disadvantage in obtaining food from sandy areas but at an advantage among the rocks where strength is required. He concluded, "Here are only two causes enumerated which might serve to create, as it were, a new species from an old one. Yet they are perfectly natural causes, and such as I think must have occurred, and are possibly occurring still. We know so very little of the causes which, in the majority of cases, make species rare or common that there may be hundreds of others at work, some even more powerful than these, which go to perpetuate and eliminate certain forms 'according to natural means of selection'".

The temptation to record an amusing incident which happened at one of the meetings of Section D at Manchester cannot be resisted. Work was proceeding smoothly under the genial guidance of Prof. Newton when, suddenly, Dr. Samuel Haughton of Dublin entered and from the back of the room announced in arresting tones that he had an important communication to make about the animals preserved from the Flood. He believed that Mrs. Noah strongly objected to her husband's intention to take the elephants on board, fearing that their weight would cause a dangerous displacement of the Ark's metacentre.

How this domestic difference was composed we had no opportunity of learning, for as the chairman, whose expression combined sympathetic amusement with mild deprecation, was rising and about to protest, Dr. Haughton, anticipating the result, had already turned towards the door, telling us over his shoulder that he was on his way to make a fuller communication on the subject to the Anthropological Section.

ACQUIRED CHARACTERS

After this brief description of an event, which I hope you will agree ought not to be forgotten, we must return to organic evolution and to one of the most important subjects debated at any time before a meeting of the British Association—the question, “Are Acquired Characters Hereditary?”—brought before the world by Prof. August Weismann, who was present at Manchester and spoke in the discussion (unfortunately not reported), introduced by Ray Lankester, in which Dr. Hubrecht, Patrick Geddes, Marcus Hartog and I took part. Weismann’s conclusion that “acquired characters” are not inherited was held by Prof. E. S. Goodrich, in his address to Section D at Edinburgh in 1921, to be “the most important contribution to the science of evolution since the publication of Darwin’s ‘Origin of Species’”, an opinion with which the great majority of biologists will agree, although the terms employed for the two classes, the inherited and the non-inherited, together with the ideas underlying them, were shown by Adam Sedgwick, at Dover in 1899, Archdall Reid, and others, as well as by Goodrich himself, to be incorrect. Nevertheless it will probably be impossible to abandon the word ‘acquired’, employed by Erasmus Darwin (1794), Lamarck (1809), and Prichard (1813) as well as by later authorities. Whenever environmental conditions are followed by characteristic changes, absent when these conditions are absent; or when such changes follow the use or disuse of the parts of an organism, or the education it has received, then we have before us the ‘acquired’ characters maintained by Weismann to be incapable of hereditary transmission. This vital conclusion, accepted, as I believe it is, by nearly all biologists, is not appreciated as it ought to be by the general public. A brief statement of a single piece of evidence may convince some who are doubtful about a conclusion with which human life is very deeply concerned.

My old friend the late A. A. Macdonell, professor of Sanskrit at Oxford, spoke two languages, English and German, as they are spoken by native Englishmen and Germans. I asked him whether he thought it was possible for any mature person to learn a foreign language so perfectly that he would be mistaken for a native. He replied that he was sure it could not be done, and that his own ability to speak the two languages as he did had been only made possible because as a small child he had been continually taken backwards and forwards between the two countries. Yet any human being transported as a baby from his own country to another and brought up there among the natives will learn to speak as they speak. All the past generations, however many, during which his ancestors spoke the language of his birthplace, will count for nothing, will not retard his acquisition of another tongue or modify it in any way.

An interesting and amusing example is provided by the futile striving of an Englishman to pronounce the Welsh double-l, generally attempted by the substitution of ‘th’. Even the advice given by a Welsh clergyman to the English bishop of his diocese is unlikely to bring success: “You must put the tip of your Right Reverend tongue against the roof of your Right Reverend mouth, and hiss like a goose”.

The result of education as an ‘acquired’ character in the Weismannian sense is of such special importance that I think it is well to quote the conclusions stated by Ray Lankester in his address to the seventy-fifth meeting of the Association at York. He then maintained that the “power of building up appropriate cerebral mechanism in response to individual experience, or what may be called ‘educability’, is the quality which characterises the larger cerebrum and is that which has led to its selection, survival and further increase in volume . . . ‘Educability’ can be transmitted; it is a congenital character. But the *results* of education can *not* be transmitted. In each generation they have to be acquired afresh. . . . On the other hand, the nerve-mechanisms of instinct are transmitted, and owe their inferiority as compared with the results of education to the very fact that they are *not* acquired by the individual in relation to his particular needs, but have arisen by selection of congenital variation in a long series of preceding generations”¹⁴.

Lankester was led by these conclusions to reject altogether the theory of G. H. Lewes, G. Romanes, and others, “that instincts are due to

lapsed intelligence", a theory also disproved by Lloyd Morgan's observations on young birds described by him at the Ipswich meeting in 1895¹². Another very important subject brought forward by Lankester was the evidence, originally published by him in 1894¹³, that Lamarck's first and second laws of heredity "are contradictory the one of the other, and therefore may be dismissed". His statement may be briefly summarized as follows:

The first law assumes that in spite of thousands of generations during which a normal environment has "moulded the individuals of a given species of organism; and determined as each individual developed and grew 'responsive' quantities in its parts (characters); yet, as Lamarck tells us, and as we know, there is in every individual born a potentiality which has *not* been extinguished. Change the normal conditions . . . and (as Lamarck bids us observe), in spite of all the long-continued response to the earlier normal specific conditions, the innate congenital potentiality shows itself. The individual . . . shows *new* responsive quantities in those parts of its structure concerned, new or acquired characters".

"So far, so good. What Lamarck next asks us to accept, as his 'second law', seems not only to lack the support of experimental proof, but to be inconsistent with what had just preceded it. The new character which is *ex hypothesi*, as was the old character . . . which it has replaced—a response to environment . . . is, according to Lamarck, all of a sudden raised to extraordinary powers. The new or freshly acquired character is declared . . . to be capable of transmission by generation; that is to say, it alters the potential character of the species. It is no longer a merely responsive or reactive character, determined quantitatively by quantitative conditions of the environment, but becomes fixed and incorporated in the potential of the race, so as to persist when other quantitative external conditions are substituted for those which originally determined it".

The effect of Lamarck's laws on the hereditary transmission of acquired characters would be this: "a past of indefinite duration is powerless to control the present, while the brief history of the present can readily control the future".

After hearing a very condensed statement of conclusions so essentially bound up with the progress of organic evolution, I feel sure that you will wish to be reminded of Prof. Ewing's words which followed the address at York:

"Now is the winter of our discontent made glorious summer by this Ray of Lankester".

Returning to the unreported discussion on the inheritance of acquired characters at Manchester, I venture to bring forward certain observations opposed to a belief in Lamarckian evolution by means of inherited experience—observations which I then described and have not known to be answered. In the relationship between enemy and prey there is very commonly no opportunity for the latter to learn by experience. The wonderfully elaborate adaptations by which sedentary insects are hidden from enemies have been evolved, not by experience of enemies but by avoidance of enemies. In these examples—and they are numberless—we are driven to accept Weismann's conclusion and with him to invoke "the all-sufficiency of Natural Selection".

When one of the twig-like caterpillars, of which there are so many in Great Britain, is detected by an insectivorous bird, it can do nothing and is devoured at once. Its one defence is the astonishingly perfect resemblance to a twig of the bush or tree on which it lives. It is firmly fixed and its weight also supported by an almost invisible thread so that it cannot escape as many caterpillars do by dropping to the ground and sheltering in the grass or among dead leaves. Its one chance of survival is to gain so perfect a disguise that it will not be seen, and to gain this end the adaptive devices are most elaborate and wonderful: its twig-like shape and colours, with the power of gradually adjusting these so as to resemble the bark of the bush or tree on which the parent moth laid the egg from which it came, even the power to reproduce exactly the appearance of lichen, the rigid stick-like attitude maintained during the hours of daylight. Finally there is the evidence, recently obtained by Robert Carrick¹⁴, that the disguise *does* protect; for examples of one of these caterpillars, resting on a branch of its food-plant fixed over a wren's nest containing young, were unnoticed by the parent bird which used the same branch as a convenient perch; yet seen and at once taken when placed on a white surface below.

One of the best examples of a prophetic instinct is to be found in the larva of an African Tabanid fly (*T. biguttatus*). This maggot lives and feeds in soft mud which, during the dry season when the chrysalis stage has been reached, will be traversed in all directions by wide and deep cracks in which insectivorous animals can search for prey. But the maggot, while the mud is still soft, prepares

for this danger. By tunnelling spirally up and down it makes a line of weakness which will cause a pillar to separate from the mass when the mud hardens and contracts. It then tunnels into the still soft pillar and becomes a chrysalis in the centre of its deeper end. However wide the cracks which appear in the mud, the maggot has arranged beforehand that they will not invade its cylinder. Dr. W. A. Lamborn, who made this most interesting discovery, observed that the summits of the pillars, forming circular disks of about the size of a penny, scattered here and there over the surface, were never thus traversed, but that an empty shell was protruding from the centre of each when the fly had emerged¹. My friend the late Prof. J. M. Baldwin, the distinguished American psychologist, well remembered at many of our meetings, wrote when he heard of this discovery: "it seems *complete*—one of those rare cases of a single experience being sufficient to establish both a fact and a reason for the fact! It is beautiful".

I would ask any believer in Lamarckian evolution, or in Hering's and Samuel Butler's theory of unconscious memory residing in the germ-cells, how it would be possible to explain these prophetic instincts, adapted not to meet but to avoid future experience, except by the operation of natural selection.

The appeal to orthogenesis, or internal developmental force, as the motive cause of evolutionary progress, has often been made—generally by palaeontologists rather than by the observers of living forms. Any such belief in the potency of an internal tendency is, I think, open to the criticism made by Thiselton Dyer in his address to Section D at Bath in 1888: "This appears to me much as if we explained the movement of a train from London to Bath by attributing to it a tendency to locomotion. Mr. Darwin lifted the whole matter out of the field of mere transcendental speculation by the theory of natural selection, a perfectly intelligible mechanism by which the result might be brought about. Science will always prefer a material *modus operandi* to anything so vague as the action of a tendency".

MENDELISM

It is not necessary for me to speak on the rediscovery of Mendel's great work and all that it has meant to our biological sections in the early decades of the present century. The recent developments, following the work of Haldane, R. A. Fisher and others, and the vitally important

relationship between Mendelism and natural selection were brought before us last year in Julian Huxley's illuminating address to Section D. The older belief that only large variations, or mutations as they then began to be called, were subject to Mendelian inheritance, and that small variations were not inherited at all, disappeared when further researches proved that extremely minute differences were "heritable in the normal manner"², and, with this, the foundation of Darwinian evolution became immensely strengthened. It is also right to remember that Bateson, the leader of Mendelian research in Great Britain, always believed in natural selection, regarding it indeed as self-evident and not very interesting. Also that Ray Lankester, as long ago as his 1906 address at York, maintained that however far Mendelism was advanced, it "would not be subversive of Mr. Darwin's generalisations, but probably tend to the more ready application of them to the explanation of many difficult cases of the structure and distribution of organisms".

The relationship between the germinal foundation of Mendelian and Weismannian heredity was considered in a paper by L. Doncaster read before Section D at the South African meeting in 1905. He then maintained that Weismann's "hypothesis that the material bearer of hereditary qualities is the chromatin of the nucleus" of the germ-cells had been confirmed by recent work on their maturation, which "has shown that they contain a mechanism which seems precisely adapted to bring about that segregation of characters which forms the most fundamental part of the Mendelian theory, and it seems hardly possible that the two things are unconnected". MacBride also in his address to the same section at Newcastle in 1906, spoke of the "great epoch-making discovery of experimental embryology, viz. the existence of *specific organ-forming substances*".

These fundamental discoveries bring to mind a conversation with Weismann when he had been finally driven to frame and elaborate this hypothesis, and was so appalled by the number and minuteness of the material bearers of hereditary qualities contained in a single germ-cell that, as he told me, he could not believe that the physicists and chemists were correct in their conclusions about the size of the atom. He admitted that diverse lines of evidence led to the same result, but even so, he believed the future would prove that physicists were mistaken and that the atom was far smaller.

NATURAL SELECTION To-day

It is impossible to say more than a few words about the very interesting and important discussion on "The Present State of the Theory of Natural Selection" held at the Royal Society on May 14 last year. The subject was approached from many points of view by both zoologists and botanists, and their conclusions were very welcome to Darwinians who remembered the earlier opinions expressed when Mendel's great work was rediscovered. I think, however, that Prof. D. M. S. Watson, in the opening address, was inclined to underestimate the value of the existing evidence for a "selective death rate", although everyone will agree that "any new evidence . . . or indeed any suggestion of cases which might be capable of investigation", would be most desirable.

I may briefly mention a few experiments brought before Section D at the Bristol meeting in 1898, beginning with the work of Weldon and Thompson on the common shore crab, showing that the effect of china clay and other impurities in the sea at Plymouth was selective and promoted changes of shape which ensured that the water flowing over the respiratory surface was more efficiently filtered.

Then, on the subject of chance, the heroic help rendered by Mrs. Weldon, who four times recorded the result of 4,096 throws of dice, showing that the faces with more than three points were, on the average, uppermost slightly more often than was to be expected. It comes back to me very clearly because of the interesting explanation—that the points on dice are marked by little holes scooped out of the faces, and that points 6, 5, and 4, respectively opposite 1, 2, and 3 are somewhat lighter, more of the ivory having been removed; also because of Francis Galton's delight and his humorously expressed wonder whether the facts had been realized by those who had an interest other than scientific in the throwing of dice.

Experimental evidence was also submitted by Miss Cora B. Sanders (Mrs. C. B. S. Hodson) and myself, proving that when the rough, angular pupa of the small tortoiseshell butterfly "is suspended from a surface against which it stands out conspicuously, it is in far greater danger than when it is fixed to one upon which it is concealed".

To the observer of living creatures, however, the most convincing evidence is provided by animals themselves. When a wild bird is seen to

capture some conspicuous butterfly or moth and then immediately to reject it, the association between inedibility and a warning colour is more convincingly suggested than when insects are offered to animals in confinement, although such experiments are of great value and often provide the only available evidence. There are, however, instances in which abundant data for statistical investigation are furnished by the wild animals themselves. Thus the long-eared bat has the convenient habit of eating moths—its regular food—while it hangs suspended from a surface to which it returns after each capture; and as the wings are rejected, these may be collected in large numbers, yielding valuable information on the significance of concealing and warning patterns.

In the attempt to determine the motive causes of organic evolution, the work of the naturalist, the student of living nature, is essential. His task is to do what Lyell did for geology by directing attention to the forces now in operation and seeking with their help to interpret the past, and in this work it is especially valuable to study adaptations which have been developed in recent times and can, in certain instances, be proved to undergo changes even now. Thus the interesting observations of H. Lyster Jameson showed that a pale local race of the common mouse had been formed, although incompletely, in 100–125 years, by the selective attacks of owls and hawks on sandhills near Dublin²⁰. I therefore believe that the colours of animals provide one of the most fruitful fields in which to pursue these investigations, and I regret that this work has been recently attacked by an American zoologist who, referring to the recent revival of natural selection, continues—"if the doctrine can emerge minus its sexual selection, its warning colors, its mimicry and its signal colors, the reaction over the end of the century will have been a distinct advantage"²¹. It is of course impossible to discuss, on the present occasion, this confident attempt to depreciate the value of work associated with the names of Bates, Wallace, Trimen and Fritz Müller. I will only point out that their conclusions on warning colours and mimicry have been immensely strengthened and confirmed by the later observations of Guy Marshall, W. A. Lamborn, St. Aubyn Rogers, Hale Carpenter, V. G. L. van Someren and others in Africa; by the experiments conducted by some of these naturalists, and also by H. B. Cott and R. Carriek, and in the United States by Morton Jones.

It is interesting to remember that a paper by two American entomologists²³ was among the first to accept and support by fresh observations the conclusions brought forward by H. W. Bates in his great memoir on the mimetic butterflies of the Amazon valley²², and that one of the authors treated the same subject more completely in a later paper²⁴ much appreciated by Darwin²⁵.

It is also important to remember that the above-mentioned conclusions have been reached by the study of marine animals no less than terrestrial, as was shown by Herdman in his address to Section D at Glasgow in 1901, and by his experiments communicated to the same section at Ipswich in 1895; also that Garstang, with his very long and intimate experience of marine life, adopts the same interpretation of colour and form with the associated attitudes and movements.

If time permitted it would be possible to speak of numerous papers on mimicry and the related subjects which have been brought before our meetings. It is impossible to attempt this now, but many will feel with me that the name of the late Dr. F. A. Dixey should not be forgotten—one who attended so regularly, so often read papers at our meetings, presided over Section D at Bournemouth in 1919, lectured at Leicester in 1907, always giving the results yielded by the study of his favourite insects, and their interpretation by the theory of natural selection; also one who delighted in the social gatherings of his Section.

MAN AND ANIMALS

In my concluding remarks I am anxious to refer to a very interesting and encouraging subject—the feeling for animals and the care for their welfare to-day, as contrasted with the treatment they received a hundred years ago and even in the youth of many among us. Only last autumn, *The Times* of October 12 reported that 1,000 swallows had arrived at Venice “sent there by bird-lovers from Vienna and Munich in order to save them from the effects of the cold weather. Soon after their arrival they were set free and flew south along the Adriatic coast”. A little earlier the writer of the amusing ‘fourth leader’ referred to a meeting of the Society for the Preservation of the Fauna of the Empire at which the care of the opossum was discussed, comparing this with the report of happenings a hundred years earlier when there was a “humorous debate” at the Zoological Society “about puffing cigar-smoke into

the cages of the monkeys”, to their evident discomfort. The writer, yielding too far, we hope, to the depression of the present day, concludes: “The world, it may be, is ‘man-sick’ and yearning to be rid of a bad mistake. But the creature cannot be wholly vile when instead of torturing monkeys it takes thought for the opossum”.

It would not be right to quote from a century-old report without speaking of all that is done and has been done during many years for the care and health of animals by the great London Society, and in doing this, for the education and happiness of our people. But the change of which I have spoken is most deeply impressed on those who remember, as many of us do, the misdirected hours in youth when birds were shot in our gardens and brick traps made to catch them. I feel sure that those who did these things are not essentially different from their children and grandchildren who have grown up in a kinder atmosphere.

I must not occupy more time on a subject which to some may seem inappropriate, but it is bound up with education in its true sense—a leading out—and if, as Ray Lankester said at York, and we are all coming to believe, the hidden powers within *are* inherited while the results of their development are *not*, then there is no easing of the burden with the passage of time, but each generation afresh must bear the heavy responsibility of conducting this development in the best way so that its successor may be able to meet the changing and, at this time, the increasing needs. The relationship between the powers within and their development was suggested in arresting words by the late Prof. Scott Holland: “To say that a man cannot be made good by Act of Parliament is such an obvious truth that people forget what an outrageous lie it is!”

INTERNATIONAL PEACE

Thoughts on the development of these hidden powers by the educating influence of social environment, suggest the greatest of the problems by which we are faced—the end of international war. Michael Foster, in his address at Dover in 1899, after speaking of progress in the material of warfare was led to believe that, “happily, the very greatness of the modern power of destruction is already becoming a bar to its use, and bids fair—may we hope before long!—wholly to put an end to it; in the words of Tacitus, though in another sense, the very preparations for war, through the

character which science gives them, make for peace". In his concluding pages he expressed the hope that the brotherly meeting between the English and French Associations at Dover and Boulogne might be looked upon as a sign that science, by nobler means than the development of armaments, was steadily working towards the same great end. In a time of still greater need and perplexity, may we not, in the same hopeful spirit, look upon the recent visit by which members of the French Association have honoured us, and feel strengthened in the belief that the great end will be reached.

There are, I know, very many people who look upon the Great War with later wars and rumours of wars as the close of Michael Foster's dream. The words in which Sir Arthur Schuster concluded his address at Manchester in 1915, and Sir Edward Thorpe at Edinburgh in 1921, indicate, I hope, that the British Association does not thus despair, and in this belief I bring before you a passage from the far earlier address which Sir Richard Owen delivered to the twenty-eighth meeting at Leeds in 1858—a passage which makes a special appeal at a time when the British and American Associations are confidently hoping to strengthen still further the bonds of sympathy and mutual appreciation by which they have been happily united for so many years.

Referring to the trans-Atlantic telegraph, Sir Richard said:

"We may confidently hope that this and other applications of pure science will tend to abolish wars over the whole earth; so that men may come to look back upon the trial of battle between misunderstanding nations, as a sign of a past state of comparative barbarism; just as we look back

from our present phase of civilization in England upon the old border warfare".

Confident words inspired by the forging of a new link between the two great English-speaking nations. Nearly eighty years have passed since they were spoken, but with all the terrible disappointments there has been great progress, and a time will surely come, and may it come quickly, a time which shall prove that the visions of the young and the dreams of the old were prophetic of a glorious reality.

Summaries of Addresses of Presidents of Sections*

Noise and the Nation

THE programme in Section A (Mathematical and Physical Science) this year is largely devoted to some of the social and industrial developments of applied physics. The president of the Section, Dr. G. W. C. Kaye, has broken with precedent in giving an address of an experimental character, and in choosing an acoustical subject for the first time in the history of the Section, extending over a hundred years.

Acoustics was long the Cinderella of the physical sciences, but with the coming of the gramophone, radio, broadcasting and the talking pictures, and the popularizing of the telephone, the commercial value of applied acoustics must now run into very large figures. Sound has become a marketable commodity, the cultural and political developments of which, particularly in regard to broadcasting, it is not easy to envisage. The literature is immense and the terminology large and extensive, as may be gathered from the recently published acoustical glossary of the British Standards Institution.

Simultaneously with these developments in applied acoustics, the nation has begun to take notice of the growth of noise—a by-product attributable in great part to an increasingly mechanized civilization. Much research is being carried out to meet the public demand for greater protection against the noise nuisance of to-day, chief interest being probably centred in the noises on the road and the noises experienced in modern buildings, which are admittedly not so quiet as those of a generation ago.

It is only within the last few years that practicable instruments have become available to measure and analyse sounds and noises, though it cannot be said that finality in these directions has been reached. In cases of annoyance caused by noise, experience indicates that while the composition and the psychological aspects are not to be ignored, sheer loudness is often a determining factor. Particular attention has therefore been devoted to the subjective scale of loudness and its unit, the phon, and the associated unit of energy or pressure level, the decibel. An important step was taken this year when both were adopted as international units by some thirteen nations in Paris.

The study of the general question of noise transmission, particularly in buildings, is more complex than might be imagined, and some of the major difficulties are not yet completely resolved. For the purpose, facilities such as are provided by the 'sound-proof' acoustic laboratories at the National Physical Laboratory have proved to be necessary. *Inter alia*, it already appears that special designs of double floors, double walls and double windows, which have been evolved, form material contributions to noise-abatement in buildings. The degree of public interest in the general question is illustrated by the wide variety of noise problems submitted to the National Physical Laboratory during the last few years: for example, the mitigation of the noises in aeroplane cabins and engine-testing factories, trains, ships, tube railways, motor-cars, motor-cycles, motor-buses, motor-horns, pneumatic drills, printing works, transformer sub-stations, cathedrals, assembly halls, business offices, flats, miniature rifle ranges, building operations and so on.

The growing volume of road traffic and the ever-increasing speed and acceleration of individual vehicles are major contributory factors to the problem of road transport noise. A Departmental Committee of the Ministry of Transport was appointed in 1934 and has since published three reports. Loudness measurements, many thousands in number, were conducted for the Committee by the National Physical Laboratory on the overall noise of some hundreds of motor-vehicles, both new and old. The Committee has proposed noise limits, which, while making very moderate demands on most types of vehicle would, by ruling out the flagrant offenders, help to ensure a standard of acoustical decency on the roads of Great Britain. More recently, the Committee has submitted a report on motor-horns.

Organized steps are being taken in Great Britain to further the abatement of the many types of unnecessary noise. There is now a goodly list of 'silent' appliances in everyday life, though it is evident that as regards many commercial machines and processes we shall have to put up with second-class expedients for the present. It is evident, however, that the finding of practicable solutions to the many ramifications of the noise problem would be welcomed by almost every section of the community.

* The presidential address, and addresses by the sectional presidents, are being published as "The Advancement of Science, 1937" (Nottingham: B.A. Reception. London: Burlington House.) 3s. 6d.

Researches in Chemotherapy

CHEMOTHERAPY, which forms the subject of Dr. F. L. Pyman's presidential address before Section B (Chemistry), may be regarded as the treatment of disease by chemical substances, which have been shown by biological methods to be relatively much more toxic to pathogenic organisms than to human or other animal hosts.

Chemotherapy was developed by Paul Ehrlich, and its most outstanding achievement has been the introduction of the arsenic group of spiröchætidicides.

In the field of bactericides, the introduction of phenol as an antiseptic by Lister in 1867 has led to the study of many derivatives of phenol. Recently systematic studies of various homologous series of phenols have resulted in the introduction into medicine of hexyl-resorcinol and amyl-*m*-cresol, the latter having a Rideal-Walker co-efficient of 280.

The chemotherapeutic investigation of amœbiocides was greatly facilitated by the *in vitro* test for amœbicidal efficiency developed by Dobell and Laidlaw. Using this test, Coulthard studied a series of alkyl derivatives of harmol prepared in Messrs. Boots' laboratories and showed that peaks of bactericidal efficiency were reached at butylharmol for *B. typhosus* and at amylharmol for *S. aureus*, whilst peak amœbicidal activity was found in *O*-*n*-nonylharmol. Salts of members of this series were, however, very sparingly soluble in water, and in order to obtain more soluble compounds the corresponding dialkylamino derivatives were prepared and their amœbicidal activities compared with that of emetine. Although the most active member was not as active as emetine, it had several times the activity of *O*-*n*-nonylharmol and it was suspected that the harmol residue might not be the important contributor to the amœbicidal properties of the molecule and that the dialkyl-aminoalkyl group might play an important part. This led through various intermediate stages to the preparation and study of a series of tetra-alkyldiamino paraffins and of these α -tetra-*n*-amyldiaminodecane was found to be the most efficient. For brevity, the compound is referred to as T.A.D.D.

The preceding results had shown that, when tested by the Dobell and Laidlaw technique, T.A.D.D. was the most active amœbiocide so far prepared. It now became necessary to compare the efficiency of this compound with that of emetine under conditions as similar as possible to those found in the intestine of a dysenteric patient. When tests were carried out under these conditions T.A.D.D. was found to be more active than emetine. As originally pointed out by

Ehrlich, the therapeutic value of a substance is a function of its toxicity to both parasite and human host. It became necessary, therefore, to determine the relative toxicities of T.A.D.D. and emetine to mice. The results of such a test showed T.A.D.D. to be from one third to one eleventh as toxic as emetine, depending on the method of administration.

T.A.D.D. had thus a greater *in vitro* amœbicidal activity and was less toxic to mice than emetine. These results appeared to justify the clinical trial of the compound in the treatment of amœbic dysentery.

Such a trial was carried out by Prof. Warrington Yorke, at the request of the Therapeutic Trials Committee of the Medical Research Council. Unfortunately, T.A.D.D. proved to be too irritant for parenteral administration and it was not sufficiently active to be of any real value when given orally.

Whilst this investigation has not yielded a compound of clinical value, it has resulted in the accumulation of valuable data which will be of value in further work on this subject.

The account of such an investigation indicates the enormous amount of chemical and biological team work involved in attempts to evolve new drugs for the treatment of disease.

The Glaciation of the Midlands

IN his address to Section C (Geology), Prof. L. J. Wills discusses the Pleistocene history of the West Midlands with the object of discovering how many glaciations are represented, and of linking these up with the better-known sequences of East Anglia.

It has long been recognized that the boundary between the 'Newer' and 'Older' Drifts crosses the district from Church Stretton through Bridgnorth to Wolverhampton. Prof. Wills devotes attention mainly to the Older Drifts, which have undergone enormous denudation in the vales but have in varying degrees survived on the Midland Plateau and on watershed areas. The evidence of the former great extension of the present outcrops is scattered, but is *en masse* sufficient to allow the assumption that the vales of Severn and Avon were ice-filled during the older glaciations, though it must be realized that they were far shallower then than now.

In the Midlands three principal types of drift can be recognized: *Irish Sea* in the north-west, and belonging to the Newer Drifts; *Western* or *Welsh* on the Midland Plateau (this occasionally contains Irish Sea boulders, and in the Trent

valley is *Pennine*, not Welsh, in origin); *Eastern* to the east of the Warwickshire Coalfield and in the Avon vale as far down as Stratford and possibly as far as Tewkesbury. The Eastern Drift is a continuation of the Great Chalky Boulder Clay of the Eastern Midlands and East Anglia.

Analysis of all the available evidence leads to the conclusion that the Older Drifts of the Midlands are the products of two separate cold periods. In the First Glaciation, ice moving from the north-west brought Welsh and Pennine material. The Welsh lobe travelled down the Severn vale, and its marginal drainage was probably responsible for the siting of the present Lower Severn valley. Some evidence of the First Interglacial has been obtained near Coventry and Rugby, and in Leicestershire. In the Second Glaciation the 'Great Eastern Glacier' of Harmer was the dominant feature, but side by side with it was an important Welsh Ice Sheet covering the northern part of the Severn vale and much of the Midland Plateau. The influence of these two lobes can be seen in the distribution of glacial and river drifts, and in modifications of the drainage. The retreat stages of the two ice sheets can only be traced in very general outline; the indistinctness is a measure of the antiquity of the events.

The Second or Great Interglacial which closed the period of the Older Drifts and led up to that of the Newer, is represented in the Midlands in two ways: first, by vast denudation which allows us to designate the Older Drifts as 'high-level' in contrast to the 'low-level' terraces of the valleys that resulted from the erosion; and secondly, by the Kidderminster Terrace of the Severn and No. 4 Terrace of the Avon, the distribution of which makes it improbable that ice has since invaded the Midlands beyond the limits of the Irish Sea Drifts.

The Third Glaciation is represented in the north-west by the Irish Sea Drifts, and elsewhere by the Main Terrace of the Severn and its correlatives in all the tributaries, and by taele-gravels and melt-water flood-gravels. Only brief reference is made to the outstanding influence of this glaciation on Midland physiography through the establishment of the Iron Bridge diversion of the upper Severn with the resultant rejuvenation of the river due to its increased volume. This and the evidence for a fourth glacial episode can only be touched upon; and no attempt is made to deal with the latest events, the primary object being to establish the existence of two glaciations within the period of the Older Drifts, and the correlation of the second of these with the Great Eastern Glaciation of East Anglia.

Selective Action of Mortality

FOR the reasons that they furnish reliable information concerning the progress of a vast experiment which we are conducting with ourselves as the experimental material, and also that they can be appreciated only by such as can bring to their examination knowledge derived from a comparative study of different forms, wild and domesticated, in the open and under the conditions of controlled experimentation, the attention of the zoologist is directed by Prof. F. A. E. Crew in his presidential address to Section D (Zoology) to the facts and observations relating to the human sex ratio.

It is easily demonstrated that to be born is a far more dangerous adventure for the male than for the female, and that indeed the true recipe for longevity is to be born a girl. It is equally readily shown that numerical equality of the sexes in a population such as ours exists only among those individuals who belong to the ages that are associated with the reproductive prime. Among the 0-15 year olds there are more males than females. Among the 20's and over there are more females than males, and the female numerical preponderance increases with increasing age, so that among the 85's and over there are twice as many women as men. In a democracy such as ours, in which sex is supposed to be disregarded, the political power of women is not at all commensurate with their relative numerical strength.

This swing in the sex ratio from high to very low is known to be the result of a sexually selective mortality which operates to the disadvantage of the male both before and after birth, and since the severity of this mortality is profoundly influenced by a number of environmental agencies, it is possible to use the sex ratio as a measure by which a society may assess the quality of its architecture.

It can be shown that there is nothing unique about the human sex ratio, and that the forces which tend to distort it are identical with those that produce the same results in other forms. When male is contrasted with female, it becomes clear that the greater fragility of the former may be regarded as an indication of his relative lack of importance in respect of propagation. Efficiency and economy would seem to be observed by the removal of the male when he has served his purpose. Through selection the sex ratio can become adjusted to the conditions that exist in a population, and it is possible to construct a thought model of a purely genetic mechanism through the workings of which the size of the primary sex ratio is brought into harmony with the amount of mortality due to the action of sex-linked genetic lethals, to sex-limitation in the expression of

disadvantageous characters, and to the effects of sex dimorphic physiological qualities. The relation between the size of the primary sex ratio and the amount of mortality, both pre-natal and during adolescence, is such as to lead to the establishment of an optimum reproductive sex ratio among those who, in respect of purely biological properties, are newly equipped for ardent reproduction.

Changing Distribution of Population

IN noting that four chief populous regions, in 'Europe', the Far East, India and eastern North America, now contain three fourths of mankind on one eighth of the land area of the world, it is pointed out by Prof. C. B. Fawcett in his presidential address to Section E (Geography), that the peopling of the fourth of these by the great European migration of the last two hundred years is the only shift of population of world magnitude recorded within the historic period. The south temperate lands even now contain barely a fortieth of the world's population; and the other considerable migrations are merely oscillations of the margins of the four great populous regions.

A more important change is the recent growth of great conurbations. In 1801 London, with 950,000 inhabitants, was the only city which approached a million. Now there are about sixty million-cities, a dozen of which exceed five million, and which together include a twelfth of mankind. The number and population of these great conurbations are growing; and if this trend were to continue unchecked for another two or three generations, it would give a world in which a majority of the inhabitants would dwell in two or three hundred such cities.

Within the great populous areas there is also a development of a few small areas of maximum concentration, where great conurbations tend to cluster. Three such areas are noted. The chief is in Western Europe. Part is in England, where it stretches across country from South Lancashire and West Yorkshire to Essex and Sussex and gives this belt of country a mean density of three thousand persons per square mile. It is continued beyond the Strait of Dover to the Rhineland. A second such area, of similar extent but half as populous, lies along the coast of the Middle Atlantic States of the United States of America, where a fifth of the population dwells on a hundredth of the area of the country in an urban zone from Boston to Washington. A third is appearing along the lower Yangtze in China.

There is as yet no comparable development in India.

Somewhat more recent in its development is the widespread retreat of population from 'regions of difficulty', marked by the diminution of population in all the highland areas of Britain and Europe and in the semi-arid parts of Australia and North America. Both changes are ascribed mainly to improvements in agricultural science and in transport, which make the cultivation of such marginal lands both less necessary and less attractive. This change is aided by the check to the natural growth of population in all the lands of Western civilization; for the rapid increase in numbers which has been a dominant fact of human life during the past two hundred years, during which mankind has increased from about 500 millions to some 2,000 millions, is now coming to an end. But there is as yet no indication that this check to growth is affecting the trends of movements discussed, which result from the development of applied science.

Economic Research and Industrial Policy

THE rationalization and planning movements, unofficial and official, that have in recent years swept over the industrial world involve a number of practical policies that must be separately discussed if their efficiency is to be scientifically assessed. In his presidential address to Section F (Economic Science and Statistics), Prof. P. Sargant Florence reviews recent realistic research into the policies of the siting, size and scope of industries.

A policy of siting or location has been urged upon the Government in connexion with the redevelopment of the depressed areas. Economic research has had to devise methods of measuring the degree of localization of all industries in the various regions of England and Wales and is now nearer a position to specify what industries can be developed where employment is still stagnant. In general, the extreme localization of industries at the source of fuel or of the existing supplies of skilled labour seems to have reached a limit, and the proximity to the home market to have become relatively more important.

A policy of larger-sized plants, firms or areas of control is usually implied by rationalization and planning. Recent statistical research into prevailing sizes, the trend in sizes, and comparative profits and costs in Britain, Germany and the United States does not confirm the theory that limits to size have been reached owing to organization becoming unmanageable. Size, however,

varies characteristically with different industries, and depends largely on their degree of mechanization and localization. A particularly pressing problem is the large number and the small size of middlemen and shops in the distributive trades. The lack of any official census of distribution for Britain makes calculations difficult, but it seems probable that there is one retailer for about every ten families, and, even for single commodities like tobacco or confectionery, an outlet for every twenty to thirty-five families! This appears excessive, since the smaller the sales turnover of each retailer the more profit he must charge per unit of sales to obtain a given income for himself. This raises prices and leads, in a vicious circle, to yet lower turnover.

Policies involving the scope of industry are those 'integrating' various processes, products or services under the control of one organization, or specializing upon and standardizing certain varieties. Standardization, as against integration, allows of mass production and of possibilities of increasing returns. There are difficulties in measuring and comparing the scope of plants or firms, but several recent experiments in connexion with plans of rationalization have shown the great increase in efficiency that specialization and narrowing of scope may achieve within one plant.

Policies of site, size and scope are interrelated. Large size is more manageable if of narrow scope, but difficult if sites must be scattered among the consuming population owing to the intransportability or the servicing requirements of the product. Further research along realistic and statistical lines is urgently needed if public policy or the policy of private firms is to achieve greater efficiency and save wastes of materials, mechanical power and man-power.

Research in Engineering

IN his presidential address to Section G (Engineering) Sir Alexander Gibb deals with the importance of research in the history of engineering. Recognition of this fact has been of very slow growth.

Organized research was nearly unknown until the end of the nineteenth century. Early progress was due almost entirely to individuals and learned societies, such as the Royal Society, working often in an atmosphere of public ridicule. Though the British led the way in Government recognition about the middle of the nineteenth century, it was largely due to the German example after the Franco-German War that the true value of research to the nation and industry was realized.

The Reichsanstalt and other testing laboratories had a direct effect on British policy which showed itself in the setting up of the National Physical Laboratory in 1900, leading later to the Department of Scientific and Industrial Research, which is now the focus, linking together all research going on in Great Britain.

The year 1900 is a boundary mark in the history of research in Great Britain. The National Physical Laboratory (1899) and the Engineering Standards Association (1901) were born then. The first, with the Department of Scientific and Industrial Research, of which it became a part in 1918, has grown into a body employing a staff of more than 1900 scientific workers; while the Engineering Standards Association has become an immense organization of no fewer than 870 committees with 4850 members.

Engineering, which started as an art, is now an applied science; and we look on scientific and industrial research as an essential factor in our national existence. In one generation our attitude has completely changed, from individualistic effort to co-operation and co-ordination. To-day national research departments, industrial research laboratories belonging to great firms or industries, research associations, scientific institutions and universities and technical colleges are the chief agencies which carry out the work, often in close co-operation one with another.

In the United States, the Dominions, and on the Continent progress and development have been equally revolutionary; and more so in some of the totalitarian States, where all research is centralized under State control. In Great Britain, though co-ordination and co-operation have done much to link together the various elements, we still lack a general national plan. Some form of affiliation to a central controlling body is inevitable if we are to avoid overlapping and duplication with their attendant waste of energy, time and money. This, incidentally, is especially necessary where the publication of the results is concerned. At present these are scattered in far too many different periodicals. A central clearing-house for engineering information is an urgent need.

One note of warning is sounded by Sir Alexander. The effects of research may sometimes be too sudden and revolutionary. Obsolescence may be too rapid, and vested interests may be tempted to buy up and suppress new inventions in order to save the loss their exploitation may involve to already operating plant. It would, however, be a short-sighted policy to restrict our enthusiasm for these reasons. He is satisfied that at the moment in the engineering world there are two outstanding questions, the co-ordination of effort and the promotion of intensive research.

Assam Origins in Relation to Oceania

DR. J. H. HUTTON in his presidential address to Section H (Anthropology) deals with certain aspects of the culture of the Assam hills which suggest a close association in origin with those of Oceania, and which may therefore throw some light on the general problem of the succession of cultures in the Indonesian archipelago.

The link between the cultures of the Naga Hills and of Melanesia has been brought into prominence by recent work of Prof. Henry Balfour, while the work of Dr. A. C. Haddon and others in Borneo and New Guinea affords instances enough to show a line of related cultures connecting Assam with the islands of the Pacific. To determine, however, the nature of that relation, it is advisable to concentrate on particular areas, and for this purpose the Fiji Islands, the Marquesas and Madagascar are chosen as being three widely separated points with inhabitants of varied race and culture in the Oceanic area.

In the case of the Fiji Islands, parallels with Assam are indicated in practices connected with war, head-hunting and human sacrifice, with the cult of the dead, and with beliefs in regard to the soul, and in items of material culture, in particular in regard to the Fijian national game of *veitanga*, and in some psychological aspects. In the Marquesas Islands a similar series of parallel customs is found, particularly in the practices associated with head-hunting; for example, in the separate disposal of the mandible and in the use of stone. In Madagascar a rather different parallel complex is found, though here again there is much similarity in the use of stone and in the treatment of the dead.

An important feature of Naga culture is the use by certain tribes of slit wooden gongs or xylophones. The cult associated with these gongs is in many ways closely parallel to canoe cults of Melanesia, and it is suggested that the Naga "canoe-gong" is a dug-out canoe by origin which has survived, as a musical instrument and a fertility fetish, a change of environment which inhibited its use as a canoe. The intimate association of the canoe-gong with head-hunting is particularly noticeable, as the ceremonial is very similar to that associated with the canoe in Melanesia, the main difference being that in the latter case the association is natural, since the canoe is the means of obtaining the victim, whereas in the Naga Hills there seems no direct reason for associating the "canoe-gong" so closely with the taking of heads. Further, the canoe can be, and is, used as a gong for certain purposes in the Pacific, where it is sounded by means of the

handles of the crew's paddles. A somewhat similar practice is found in Manipur, and it is suggested that the dumbbell-like implement used for pounding on the sides of a canoe-gong is a degenerate form of a paddle formerly used for propelling it as well.

The general conclusion is that not only has the culture of Assam been influenced by a stream of migration from Indonesia north-westwards, but also that in both areas, as in Oceania, a series of corresponding and related cultural strata are to be found in an amalgamated form, even if the actual site of amalgamation was elsewhere. It is suggested that such a site is to be sought for in or near the Indian archipelago.

Heat Production, Nutrition and Growth in Man

IT is almost a truism to say that the amount of money spent on medical research has greatly increased of recent years; but, as Dr. E. P. Poulton shows in his presidential address to Section I (Physiology), the application of research to medical practice has lagged behind, especially where newer and expensive apparatus is concerned, largely because of the straitened circumstances of the voluntary hospitals. A pious benefactor could accomplish much with a comparatively small sum of money if he helped the voluntary teaching hospitals in this respect, as when once the medical student—the future doctor—has become accustomed to a new method or new apparatus its spread through the country cannot be so long delayed.

Direct calorimetry means the determination of the heat in a calorimeter. Indirect calorimetry means its calculation from the oxygen absorbed and the carbon dioxide given out. At present indirect calorimetry is based on the theory that the respiratory quotient (volume of carbon dioxide given out divided by volume of oxygen absorbed) indicates the proportion of fat and carbohydrates being burnt in the organism. A comparison of the figures for heat, oxygen and carbon dioxide obtained by Benedict and Carpenter and Du Bois and his colleagues, shows that there is a fundamental error in the present method of indirect calorimetry.

The theory which best explains the facts is that carbohydrate and fat are always burnt in a fixed proportion in the organism, and that when the respiratory quotient rises there is simultaneous conversion of carbohydrate into fat,

and with a fall of respiratory quotient vice versa, as indicated by the following equation, which is based on Cathcart and Cuthbertson's analyses for human fat, and from which it follows that every litre of oxygen used in the conversion is equivalent to 3.93 calories :

A quantitative proof of this conversion (1) during basal metabolism tests, (2) after food and (3) during exercise on a carbohydrate diet is obtained from the fact that, after allowing for the heat, oxygen and carbon dioxide required for the combustion of carbohydrate and fat in a fixed proportion, the equivalence of the remaining oxygen and heat is very close to this figure.

Since these conversions are ephemeral under basal conditions, the basal metabolism should be measured by the carbon dioxide alone, and this means a new definition of basal metabolism ; an experimental method is described. It is argued that the proper standards of metabolism in adults depend on the weight and age of the individual, and that the height should not be brought in as a separate factor, as in Du Bois's height-weight formula. In babies, however, height is more important than weight, because some individuals are heavy, probably from the retention of fluid due to hypothyroidism. There are three nutritional periods in childhood : the first, up to a length of 29 inches (1 year), when the baby puts on fat and the carbon dioxide increases rapidly ; the second, from 29 inches to 41½ inches (5-6 years), when the excess of fat is lost and the metabolism only increases slightly with the weight ; and the third, from 41½ inches upwards, when the weight and carbon dioxide increases steadily. It is shown that the relation weight to age is not a satisfactory standard of growth ; but only height and age, the 'cumulative growth curve'. Although growth is greater now than it was fifty-six years ago, and children of better-class families are taller than those from poor families, the average general nutrition of the child in these groups, represented by the relation of the logarithm of the height to the logarithm of the weight, remains constant, and it is suggested that the calorie intake is sufficient ; but that certain growth factors are deficient among the poorer classes.

Tests for Colour Defects

DR. MARY COLLINS in her presidential address to Section J (Psychology) discusses some of the tests used in the diagnosis of colour defect. A brief reference is made to total colour-blindness and blue-yellow blindness, but they have

neither the same theoretical nor practical importance of the third form of the defect, namely, red-green blindness. The incidence of this latter type in the male population is quoted in recent literature at figures ranging generally from 5 per cent to 12 per cent, as contrasted with the figures usually given of 3-4 per cent, her own results giving 7.5 per cent. It does not necessarily follow that the incidence of the defect is increasing, but the indications are that the detection of the defect is now more accurate owing to the improvement of test material.

It is gradually being realized that many degrees of red-green colour-blindness exist. In its extreme form there is complete blindness to red and green, but in a milder form blindness to these two colours is only partial. Red and green can be discriminated if conditions are favourable, but when unfavourable conditions exist, as in mist or fog, these colours are confused. The anomalous trichromate forms one type of the partial colour-blind. The suggestion is made that provided the colour perception so far as red and green are concerned of a sufficient number of individuals could be examined, a continuous series ranging from normal, that is, perfect perception of these colours, to extreme red-green colour-blindness might be found. The intermediate forms, which although not totally blind to red and green show great deviations from the normal, are very important.

Tests for colour defect fall into two categories ; in one type of test, transmitted light is used, in the other reflected light. While the former is regarded as the more fundamental, the latter can be of great service for quick diagnosis of colour anomaly. As a spectrometric examination is not always possible, either some form of lantern test or pigment test is substituted. Both are essential in posts where lack of accurate colour discrimination involves danger to the community. The former, using coloured lights, brings conditions nearer to practical conditions. In other posts, however, a pigment test is all that is essential. To this end, a combination of the Ishihara test, the first three tables of the Stilling test and Schaaff's mosaic plates is recommended.

A detailed examination of a number of pigment tests has been made. The responses of a group of colour-blinds have been compared with the responses of a control group of individuals with normal colour vision. In this way an evaluation of the tests has been made possible. Some of the tests, too, have been submitted to filter analysis.

Inconsistencies have appeared. It may be that the discrepancies revealed are due to numerous deviations from the normal in colour vision, and that we are not dealing with linear variations in

degree, but with multidimensional variations. A wide new field for investigation is thus disclosed, the working of which may yield valuable results for the whole theory of colour vision.

Education and the Modern Study of Plants

THE subject of Prof. E. J. Salisbury's presidential address to Section K (Botany) is the modern study of plants in relation to education. There are several misconceptions with respect both to the contacts and to the contents of botanical science. Despite the vastly enlarged content of botanical knowledge since it was regarded as a harmless and elegant occupation for the female sex, the general conception of botany has remained much what it was then. The high value of botany as an educational subject and indeed its absolute necessity in any system of real cultural development is an aspect that botanists have failed to present and emphasize. This is partly the outcome of the growing obtrusion of the more technological aspects in this as in other subjects; a trend which is making itself felt further and further back in the student's training, at the expense of general education and culture. Here, as elsewhere, too much attention is paid to the acquisition of mere information, too little to the principles which are involved.

Our educational methods are too often divided in their allegiance between the provision of a liberal culture that will make for the greatest happiness of the individual in terms of mental contentment and an abiding resource in later life, and the technical equipment of the student for the earning of his daily bread. This emphasis on erudition has been perhaps encouraged by the universities through the fact that a sufficiently broad basis of scientific knowledge is not insisted upon before specialization begins, and that in the appointment to academic posts too little attention is given to capacity as teachers.

The merits of botany from the cultural point of view are many. It provides perhaps the best medium for training in accurate observation, it is the foundation of a vast extent of human activity and the basis of a large and essential part of every human environment. Its very extent, however, as indicated by enumeration of its diverse branches of taxonomy, morphology, anatomy, cytology, mycology, palaeobotany and plant geography, on the descriptive side, and the experimental aspects of ecology, physiology, bacteriology and genetics,

indicate the breadth of the botanical field, whilst the applied aspects of agriculture, horticulture, pomology, sylviculture and plant pathology show the great contribution that botany can make to the well-being of the human race as well as to the enrichment of the mind. This diversity tends towards detachment of interests and specialization which should be accompanied by greater co-ordination. The accumulation of data in these varied directions of inquiry will only fulfil its purpose if the many threads are continually woven into a single fabric of knowledge.

Herein lies the particular cultural value of the synthetic approach which we term ecology. The study of the plant in relation to its environment not only brings together almost every aspect of plant study but also has a direct bearing upon many practical problems such as land utilization, the conservation of water supplies, or the selection and care of national parks.

The Informative Content of Education

MR. H. G. WELLS, in his presidential address to Section L (Education), directs attention to an aspect of educational science that has received perhaps a disproportionately small amount of attention in educational literature, the question of information. He leaves the physical and mental training of our modern populations aside, he contributes nothing to the discussion of language teaching, mathematics, the cultivation of literary appreciation, music, drawing and aesthetic training generally, and he concentrates upon the question of what a modern human being should know in order to play the part of a citizen, happily and adequately. What sort of *fact system* should be and can be established in a normal human mind under the conditions existing in a contemporary civilized community?

Few people realize the restrictions set to the accumulation of knowledge by the exigencies of the time-table and the school-leaving age. When due allowance has been made for the other elements in educational work it is questionable whether we can allot more than six hours a week to imparting real knowledge (real, that is, as distinguished from methods of expression, etc.), or, assuming ten 40-week years, rather less than two thousand four hundred hours altogether in the school period of life. A vast amount of miscellaneous knowledge is, of course, picked up by talking, reading, observation and so forth outside the formal school scheme and we learn facts in vast variety to our

dying days, but this is uncorrelated stuff, and it is within the limits of these two thousand four hundred precious hours that a sound framework of general knowledge must be established, if ever it is to be established in the growing mind.

At present we waste a considerable amount of this meagre allowance in imparting useless and unedifying information or information of secondary importance. We need a much more stringent economy in this respect and a more rigorous examination of what is included. The desire for knowledge, unless it is perverted and discouraged, is a natural impulse in the developing human being, and the informative side of educational work should be based on the natural curiosity of the child and should stimulate, develop and gratify it. The curiosity of the child turns mainly upon inanimate things and what can be done with them, upon animals and (secondarily) plants and upon personal and then social reactions. Upon the systematic exploitation of these primitive divisions of curiosity our teaching of the facts of physics, biology and historical and social sciences must rest. By a careful selection of topics it is possible in the period up to the dawn of adolescence to impart clear conceptions of material science; making for mechanical understanding and competence, and a vision of the history of life upon the earth and of human history and human conditions, hygienic, physiological, geographical and political, sufficient for adequate citizenship without any killing of the spirit of inquiry.

A much more realistic and serviceable knowledge than is generally attained, of economic life and of the legal conventions of property and of the process of finance which dominate our everyday lives, is possible before the school-leaving age, but it is possible only through the stringent elimination of any irrelevant matter and of any matter which distorts the general picture. The major fault of the knowledge system we build up to-day in the general mind is its lack of proportion. The historical intelligence, the political mind of the contemporary European citizen is a sort of hunchback mind, in which the hole-and-corner facts of the national history and the petty details of the Jewish tribal records loom, preposterously exaggerated. The necessity of a drastic modernization of the historical outlook has been shirked too long—with disastrous results to the world. History, the backbone of our fact system, needs to be straightened and that hunch removed.

Under modern conditions schooling is only foundation work. There is now no end to education throughout life. The primary fact system passes insensibly into a vast variety of technical learning and adult culture and so upward at its highest levels to the knowledge evoked by original inquiry

and creative work. The proportion of those who contribute by observation and criticism to the common stock of knowledge and to its sifting and organization is likely to increase very considerably in the future. Mass observation as it is being developed by Harrison and his group may have many important effects upon the public mentality.

State Intervention in Agriculture

IN his presidential address to Section M (Agriculture), Mr. J. M. Caie first shows the position occupied by agriculture in the State, by giving statistics of areas, holdings and populations, the output of food from our farms, and the contribution they make to the food consumption of the people. Corresponding figures for Denmark and Norway are given for purposes of comparison. Specially notable facts are that the number of persons per acre of cultivated land in Great Britain, 1.5, is relatively high, while the proportion of the population engaged in British agriculture, about 6 per cent, is very low, as compared with 29 and 30 per cent in the other two countries; that the products of animal husbandry represent about 72 per cent of the output of our land; that the value of the output per acre of land is about £8 in Great Britain and Norway, and £11 in Denmark, while the annual output per person in British agriculture is £200 and in Danish £150; that in respect of most products, except liquid milk, oats and potatoes, we require to import very considerable quantities; and that agriculture buys from other industries goods valued, roughly, at twenty to thirty million pounds a year.

State intervention may be divided into three categories: (1) compulsion, enforced by penalties; (2) provision of means for voluntary action, with powers to compel minorities; (3) assistance—financial, advisory, protective, etc. Present measures of control are such as relate to annual statistical returns, contagious diseases of animals, destructive insects and pests, live-stock breeding, agricultural wages, etc. Under the second category comes the recent marketing legislation, while under the third category particular mention may be made of State grants for agricultural education and research. In 1912 these amounted to £100,639 per annum, whereas in 1936 the corresponding figure was £765,339. During that period the only significant increases in the average yield per acre of our principal crops were about 4–5 bushels of oats and half a ton of potatoes. But many progressive farmers could show increases in excess of

the general average, and the effects of improved methods are also to be found in reduced costs of production.

Statistics suggest that British agriculture at present falls short of producing as much home-grown food as is possible and desirable for the nutrition of the people and of affording employment on the land to as many persons as is reasonably practicable. As the output per unit of agricultural labour is steadily rising, increased production may not necessarily cause increased employment, but on the other hand it will probably be long ere the large-scale mechanized farm is normal in Great Britain. Two million acres have gone out of arable cultivation since the Great War, and increased production is at present a question of making up leeway in land and people rather than of settling men on new holdings.

The amount of assistance afforded by the State to agriculture indicates a possibility that, sooner or later, greater control may be exercised over the farmer's methods and the quantity and quality of his products. Such measures might raise questions as to insurance against loss, limitation of profits, control of rent, wages, etc. If it were the permanent policy of the State to support agriculture, it might be desirable to survey the whole industry, its place in the social and economic structure of the country, its present and potential capacity to meet the food requirements of the people, and its relation to international trade.

Lastly, one must consider whether in State aid, with its attendant shadow of control, lies the only hope for British agriculture. Some, at any rate, would wish to believe that our farmers, given a fair share of the home markets, could maintain their position by their own initiative, energy and resource, and with the help that education and research, both scientific and economic, can give. Otherwise there is at least a risk that our farming may become a hanger-on of the State, dependent on its bounty and subject to its commands.

Natural History Outlook

THE natural history outlook has changed so much during the present century that a new orientation is required if natural history societies are to keep their place as an integral part of the organization of science in Great Britain. In his presidential address to the Conference of Delegates of Corresponding Societies, Prof. James Ritchie directs attention to the changes which specialization has wrought in the opportunity of original

amateur investigation, and suggests ways in which the societies might turn modern trends to good account.

Local societies perform useful work in spreading knowledge of scientific method and progress by their lecture programmes and discussions, but a higher aim is the gaining of new knowledge by regional investigations. The stable work which until now has kept the societies alive as contributors to science has been the building up of local lists. That outlet for the energy and enthusiasm of the local naturalist has become restricted owing partly to the exhaustion of opportunity for discovering rarities, and partly to the increasing subtlety of identification demanded by the modern systematist, so that the amateur has been frozen out of a province which for ages was particularly his own.

Two notable developments in the natural history outlook of the present century suggest ways in which the natural history societies may still retain their usefulness and contribute their quota to the advancement of knowledge.

In the first place, there is a marked tendency, due to the complexity of scientific problems, to forsake the individualistic form of research and to replace isolation by the collaboration of many workers organized as a team, whose joint labours converge upon some definite problem. In the second place, the emphasis of research has moved from morphological studies, which have passed far beyond the scope of the amateur, to the investigation of the animal as a living thing. A combination of these two tendencies offers a new outlook and a new field for the societies, the combination of organized co-operation or team-work directed towards the solution of biological problems. Much has already been learned by such methods, for example, about bird migration by organized co-operation in the ringing of birds in Great Britain and other countries, about the arrival and movements of birds and many other seasonal occurrences by the organized reports sent to the Royal Meteorological Society and published annually as a Phenological Report, about the migration of insects by the records sent to a committee of the South-eastern Union of Scientific Societies. Members of the societies, as individuals, already do good work in all these investigations, but more observers are required, and the societies could organize them, and could add enormously to the scope and scientific value of the inquiries of such organizations as the Bureau of Animal Population at Oxford or the Institute of Ornithology.

Should some societies lack in numbers of naturalists able to engage in such joint enterprises in biological problems, there are many other opportunities open to the individual naturalist for

the study of biological questions of real importance. Very little is known about the influence of weather and food supplies in Nature upon the development of mammals, birds, insects or, indeed, any other creature, and such studies, or the investigation of plant and animal populations in a circumscribed area, or of the changes wrought upon plant and animal groups by the interference of man, offer themselves as subjects for direct and not too difficult attack.

. A third line of inquiry suitable for the amateur naturalist lies in simple experimental zoology, exemplified by such as Darwin's tests for the intelligence of earthworms, or Lord Avebury's

experiments with bees and colours, or in more modern method Miss Ilse's experiments upon the colour preferences of butterflies.

Such investigations as have been suggested may not result in great discoveries—great discoveries lie in the lap of the gods—but for the observer they mean a training in accuracy, persistent or continuous observation, careful recording, and in the end that rigid consideration which leads from facts to general truths. To the societies, the natural history outlook will bring new vigour, and with it that satisfaction and honest pride which go with the enlarging, even in modest degree, of the bounds of knowledge.

Britain. He points out that the basic unit in British local administration is the parish, the zone of influence of a single place of worship in the Middle Ages. Rural districts, urban districts and boroughs have been built up by the aggregation of parishes, and national parliamentary representation is still organized on that fundamental unit. As a consequence, in spite of many reforms, there are still more than two thousand separate authorities responsible for local community organization. Early legislation favoured supply by a local council. This favoured the setting up of a large number of small generating stations. The work of Ferranti showed the possibilities of alternating current transmission; but the small areas resulting from the early legislation, the wide distribution of coal and its abundant supply did not give the incentive to A.C. supply that there was in other countries. In 1925, a Government committee was set up under the chairmanship of Lord Weir. The committee came to the conclusion that there was a wide difference between generation and distribution and that retail distribution was a local matter which might suitably be decentralized. The findings of this committee were the basis of the Electricity Act of 1926. A Central Electricity Board was formed to construct and operate a large number of high-tension transmission lines called a Grid. The board divided the network into nine schemes covering the whole of Great Britain except northern Scotland. Not only did the construction of the Grid have a beneficial effect upon national employment at a time of acute depression, but also the experience in high-voltage construction which it entailed has placed British manufacturers once more in the forefront of technical progress.

University's Care of Body and Mind

ROOSEVELT POLYTECHNIC INSTITUTE, founded in 1834 at Troy, New York, claims to be the oldest institution of higher learning in any English-speaking country that has devoted itself continuously to instruction and research in science and engineering. In a recent bulletin, it directs attention to the very thorough provision it has made not merely for the technical efficiency of its graduates but also for ensuring the physical fitness and bodily vigour of its undergraduates and for developing in them a broad and balanced mental outlook. Applicants for admission are examined physically; and if corrective exercises seem advisable they are prescribed by the Department of Physical Education. Every undergraduate is required to take during the first year a comprehensive course in physical education, including personal hygiene, recreational games, gymnastics, swimming and athletics. Medical advice and hospital care in case of need have been made available for all students. A member of the staff of a neighbouring hospital is in attendance daily for an hour and a half in the gymnasium for consultation. In the first year every undergraduate has to qualify in English, drawing, history, graphics, mathematics, physics and chemistry, and has to prepare a thesis during the summer vacation. The English course covers the material and methods of composition as

illustrated by the successive steps in the preparation of a comprehensive article on a subject of immediate interest, the preparation and delivery of incidental speeches and a survey of contemporary ideas and current usages. Except in the case of students of architecture, all undergraduates also take a brief course introductory to professional study, designed to acquaint them with the materials and methods of study in different fields, to introduce them to the members of the faculty whom they will eventually meet in their work, and to indicate the nature of the openings which will be available to them upon graduation.

Natural History and Science in South Australia

THE presidential address before the Royal Society of South Australia, delivered by Dr. C. T. Madigan last year, is devoted to the history of the hundred years of science in South Australia as appropriate to this centenary year (*Trans. Proc. Roy. Soc. S. Australia*, 60, Dec. 1936). He points out that the Royal Society is really older than the State itself, for though it has an unbroken existence only since 1853, its origin can be traced back to the South Australian Literary and Scientific Association initiated among the founders of the Colony in London in 1834. The active functioning of the Royal Society dates from the inspiring presidency of Prof. Ralph Tate; in the twenty-five years of his association with the Society between 1876 and 1901, it became the established medium for publication of original scientific contributions. The nature of this published work is summarized by Prof. Harvey Johnston for general zoology, by Sir Douglas Mawson on geology, by Prof. J. G. Wood and Mr. J. M. Black on botany, by Dr. James Davidson on entomology, and Dr. T. D. Campbell on anthropology. Naturally these descriptive and natural history subjects, so important in a young colony, bulk most largely in this first century, and Prof. R. W. Chapman's report, whilst reminding us that many of Sir William Bragg's first publications in physics appeared in the *Transactions* of the Society, makes it most abundantly clear why this state of affairs prevailed. Before the Society or its predecessor, the Adelaide Philosophical Society, could spend its energies upon the publication of natural history, it had to pass through a phase in which it was the public forum for the advocacy of any and every cause associated with general education. In those days, even so late as 1868, a speaker urging the establishment of free schools, could quote a South Australian parent in this strain, "I have ten children who can't read or write. I can't read or write myself, why should they?"

Zoology of Iceland

THE study of the zoology of Iceland has lagged behind the investigation of its geology and geography, but a new work in five volumes on the "Zoology of Iceland" should form a worthy contribution to the knowledge of a fauna of unusual interest from several points of view (Openhagen and Reykjavik: Levin and Nunksgaard). The work will be carried out by specialists, and each part will appear as it is

completed, so that publication will be discontinuous and will probably cover a period of about ten years. To subscribers parts will be sold at Kr. 1.00 per sheet, and the whole work is estimated to contain about 100-150 sheets. The two parts first to be published have been received—R. Spärck on "The Benthonic Animal Communities of the Coastal Waters", and E. Weesenberg-Lund on "Gephyrea". Both authors find that the fauna with which they deal consists mainly of an arctic and an arctic-boreal admixture, in which the latter predominates, and with which rare forms, such as the gephyrean *Sipunculus norvegicus*, represent a southern fauna which may have survived from a warmer period. In summing up the conclusions of his investigation, Spärck points out that the absence of a boreal shallow-water fauna seems to indicate that in post-glacial time no land connexion can have existed between Iceland, the Faroes and the continent of Europe. But the fauna itself is by no means a sparse one, since in quantity it compares favourably with the fauna of the North Sea, which is generally considered to be very productive and is richer than the corresponding faunas of East Greenland and northern Russia. This relative wealth of bottom fauna may be a dominant factor in determining the presence of a fish population, which in turn has determined the importance of the fisheries in Iceland waters.

Plants and the Dwelling-House

Most people readily admit the value of out blooms and growing plants for decoration of the home, but not all plants can make good growth in the somewhat trying conditions of the average dwelling-house. A recent publication of the Field Museum of Natural History, Chicago, is entitled "House Plants" (No. 20, 1937, 35 cents). It has been written by Mr. R. van Tress, and maintains the well-known practical outlook of this Museum's publications. Such well-tryed subjects as the *Aspidistra* (here called, most appropriately, the 'cast iron plant'), the small conifer *Araucaria excelsa*, various geraniums, and the india-rubber plant (*Ficus elastica*) are known to all. The leaflet also shows that hybrid species of *Hippeastrum*, *Hydrangea*, *Poinsettia*, *Begonia*, *Azalea*, *Primula sinensis*, heliotrope, the African violet (*Saintpaulia ionantha*), the shrimp plant (*Beloperone guttata*) and many others, including the common English ivy, are suitable for domestic conditions. They give greater and more varied beauty than the better-known species. Many illustrations enrich the leaflet, and there would seem to be no reason why the plants mentioned therein should not succeed in Great Britain as well as in the United States.

Supraconductivity

THE issue of the *Journal of the Washington Academy of Sciences* of June 15 contains the address of the retiring president of the Academy, Dr. F. B. Silsbee, of the Bureau of Standards, delivered in January. It extends to twenty pages, and deals with the additions which have been made during the last two or three years to our knowledge of the electrical

properties of metals at very low temperatures. References are given to previous summaries up to 1935 and to nearly thirty memoirs on the subject which have been published since, most of them in 1936. The original description of a supraconductor as one in which the resistivity is zero is beginning to be replaced by the newer one that the magnetic induction is zero and that any current which flows in it is confined to an excessively thin layer at its surface. The abruptness of the change of conductivity as the temperature is lowered has been investigated, and in the case of tantalum has been expressed by means of the error function. The paradox of how a magnetic field which cannot penetrate a supraconductor can still affect its conductivity is still unsolved, and the reasons for the decrease of heat conductivity and increase of specific heat in the supraconducting state have still to be determined.

Philadelphia Academy of Natural Sciences

THIS year the Academy celebrates its one hundred and twenty-fifth anniversary, and the opportunity has been taken of relating to friends and members in a special report the work accomplished during the past year. The title chosen for the report is "Discovery" (which unfortunately duplicates the name of a well-known British scientific periodical). The year was marked by the announcement of an ambitious programme which included the strengthening of the scientific work of the Academy, the inauguration of an Education Department which would correlate the work of the Academy with the public and private school system in Philadelphia, the erection of modern educational exhibits, and the re-establishment of the Department of Geology and Palaeontology. For the support of the educational programme over a five-year demonstration period a sum of \$74,915 dollars was required, and the response to the end of 1936 reached the fine total of \$241,135 dollars. Already important steps have been taken towards the accomplishment of the programme, and we note with satisfaction that the first step was to restore the reductions which had been made during the period of stress in the salaries of the staff. We join with the Academy in lamenting the death on January 22 of its president, Mr. Effingham B. Morris, who since his election to the presidency in 1928 has been the leader and stimulus in all phases of the Academy's work for science and for the community.

Peace Movements

THE "Peace Year Book, 1937" (London: National Peace Council. 2s.) contains a good deal of useful information on international affairs and should prove a reliable book of reference on the peace movement throughout the world. It includes directories of peace organizations in Great Britain, of national organizations, Anglo-foreign societies and local peace organizations as well as peace and kindred organizations abroad. The appendixes include the text of the Covenant of the League of Nations, a bibliography of books and pamphlets, notes on the reform of the League, the Mandates System, an analysis of the

armaments situation and an extensive summary by Dr. Hilda Clarke of the report of the Royal Commission on the Private Manufacture of and Trading in Arms. The first part of the book contains articles on international affairs, the situation in Spain receiving special attention, and the work of the League of Nations in 1936 is reviewed by Maurice Fanshawe. Of special interest to scientific workers is an able article in the second part of the book by J. D. Bernal on "Science and Peace", in which some account is given of the work of the Science Commission of the World Peace Congress. The general resolution on the attitude of scientific workers to war is given in full, together with the report of the Science Sub-Commission, and Mr. Bernal indicates some of the responsibilities of men of science in this matter.

Training in Domestic Science

In the *Electrical Age* of July 1, a quarterly journal published by the Electrical Association for Women, an interesting description is given by Anne R. Macarthur of the Glasgow and West of Scotland College of Domestic Science, one of the most important women's training colleges in Great Britain. There are now three hundred students taking the three years (sometimes four years) 'teaching diploma' courses. In addition to the usual household subjects are cooking for sailors and yachtmen, hygiene, etc. The college was built in 1911, the rooms being light, airy and spacious, but it was no sooner finished than it was taken over as a War hospital. During the past session, 1,697 students have attended the college for diploma courses as teachers of domestic science and as dieticians. They have the advantage of working with every type of equipment which they are likely to meet on completion of their course. Electricity figures prominently in the 24 kitchens, 5 laundries, 14 sewing rooms and in the residences and model flats of the College. The College residences are lofty houses overlooking Kelvingrove Park and all have bedrooms for one, two or more occupants, pleasantly furnished sitting-rooms and modern bathrooms. A common room with a parquet floor and softly coloured furnishings extends the full width of the building. On the roof, a bijou isolation hospital, with a small electrically equipped kitchenette offers comfort and most hygienic conditions to invalids.

Natural History in the Schools

THE annual reports of two school societies, the Marlborough College Natural History Society and the Rugby School Natural History Society, suggest that the schools are taking their due place in the training of the naturalists of the future. Both Societies have had a busy year. Marlborough has dropped from the report the local hand-lists, which must have given to young collectors many a useful pointer towards identification of species, and it has discovered that the members prefer an informal ramble to the massed expedition of a formal field day, which is all to the good from the point of view of training observation. Rugby includes long lists

of the seaweeds and marine fauna of Port Erin, which do not seem to be particularly appropriate, although the introduction on the zoning of marine forms illustrates a useful type of observation. Both reports contain records of the local fauna made by members, and both Societies have a useful credit balance on the year's accounts, notwithstanding that Rugby spent more than £400, mostly in erecting a new vivarium and in altering and redecorating the rooms of various sections.

Agricultural Research in Great Britain

THE annual reports on the work carried out at the various agricultural research institutes in the United Kingdom during 1934-35 have now been published (H.M. Stationery Office. 5s. net). The volume also includes reports of certain other agricultural investigations carried out under the auspices of the Agricultural Research Council, and an account of the research activities of the agricultural advisory officers. In view of the scope of the work described, it has of necessity been published in summarized form, but those desirous of further information will find references to the original papers in the appropriate section, and the names and addresses of the directors of the institutes to whom inquiries may be sent.

Grants for Metallurgical Research

THE Iron and Steel Institute offers annually a limited number of grants from the research fund founded by the late Mr. Andrew Carnegie in aid of metallurgical research work. The object of the scheme is to enable students who have passed through a college curriculum, or have been trained in industrial establishments, to conduct researches on problems of practical and scientific importance relating to the metallurgy of iron and steel and allied subjects. The value of the grant will depend on the nature of the proposed research work, but the maximum amount granted in any one year will, as a rule, not exceed £100. Applications for grants must be made before September 30. Further information can be obtained from the Secretary, Iron and Steel Institute, 28 Victoria Street, London, S.W.1.

Third Prehistoric Congress of the Far East

THE third Prehistoric Congress of the Far East will take place at Singapore on January 24-29, 1938. Membership of the Congress is confined to delegates nominated by their respective Governments or by scientific societies and institutions. Other anthropologists and prehistorians, however, will be allowed to attend the sessions of the Congress as visitors. They will enjoy all the privileges of members of the Congress, with the exception of the right to vote. The official languages which will be recognized are English, French and German. There is no subscription. Applications for invitation should be addressed to the Director, Raffles Museum, Singapore, Straits Settlements.

Metal-Ammonia Ions

IN connexion with the letters from F. J. Garrick and from Dr. J. S. Anderson, N. L. Spoor and Prof. H. V. A. Briscoe published in *NATURE* of March 20, 1937 (p. 507), Prof. A. A. Grünberg, Kovenaky persulok 22, log. 12, Leningrad, has been good enough to give references to several papers by himself and his collaborators which are for the most part inaccessible to English readers. In these, during the last seven years, it has been shown experimentally that the ammines of platinum and rhodium may undergo acid-dissociation by a mechanism similar to that inferred from the exchange experiments on cobalt ammines. Prof. Briscoe and his collaborators state that they are glad to learn that their entirely independent experiments afford, both qualitatively and quantitatively, so satisfactory a confirmation of the findings and predictions Prof. Grünberg has already published. Of the more recent references he gives, one (A. A. Grünberg and D. T. Rjabtschikoff, *Acta Physico-Chimica*, 3, No. 5, 555; 1935), which is in German, and may be seen in a few British libraries, should certainly be consulted by chemists interested in this subject.

Medical Research in India

THE first annual report, for 1935-36, of the Indian Institute for Medical Research has been issued by the Governing Body. The Institute in Calcutta commenced work on January 1, 1935, with a 'diagnostic' section, for helping medical practitioners, and four research departments, and a brief survey of research work carried out is given. This includes the preparation of a potent anti-choleera serum, trials of which are now being carried out, a vaccine for the treatment of oriental sore (leishmaniasis), nutritional researches, with the discovery that some common Indian fruits contain a high content of vitamin C, and the mechanism of antigen-antibody combination.

Announcements

THE second International Congress of Cosmobiology will be held at La Malou on September 19-21. Further information can be obtained from Dr. M. Faure, La Malou, Hérault, France.

THE second International Scientific Congress of Alimentation will be held in Paris in the second fortnight of October and will consist of the following six sections; physiology of feeding, rules for normal feeding, feeding in the colonies, the teaching and social importance of food hygiene, and the protection and supervision of articles of food. Further information can be obtained from M. Alquier, 16 rue de l'Estrapade, Paris 5e.

THE one hundred and fiftieth anniversary of the birth of the celebrated Czech physiologist and histologist Johannes Evangelista von Purkinje will be celebrated by a series of ceremonies and addresses at Prague, Brno and Bratislava on September 24-28. Further information can be obtained from the secretary, Dr. Jarmila Psotnicková, 32 Katerinka, Praha II.

THE Serbian Royal Academy of Sciences, which is composed of four academies—those of social science,

natural science, philosophical science and fine arts—recently celebrated the fiftieth anniversary of its foundation in the presence of the Regent, Prince Paul of Yugoslavia, Dr. Radenko Stankovitch, formerly professor of the Faculty of Medicine at Belgrade, the Patriarch of the Orthodox Church, and a number of other well-known scientific workers and high officials of the Balkan countries.

THE library of the Radcliffe Observatory, Oxford, is about to be transferred to its new quarters in South Africa, and publications intended for it should now be addressed to "The Radcliffe Observatory, Pretoria, South Africa", instead of to Oxford.

A LECTURE COURSE on industrial law has been arranged by the Industrial Welfare Society at its headquarters, 14 Hobart Place, S.W.1, beginning on October 4 at 6.30 p.m., for ten weeks, and will be conducted by Mr. H. Samuel, barrister-at-law. Further information can be obtained from the secretary of the Society.

AN exhibition of Egyptian antiquities newly found at Arment by the Sir Robert Mond Expedition has recently been arranged at the Archaeological Institute, St. John's Lodge, Regent's Park, London, N.W.1, by the Egypt Exploration Society. The exhibition will remain open until September 25. Admission and catalogue are free.

WE have received a communication from the Secretary of St. Joseph's House, Diocesan Home for Boys (a home for orphan and destitute boys), 126 Baker Avenue, Salisbury, Southern Rhodesia, stating that it is proposed to encourage the boys in the study of science, including microscopy. The Secretary would be grateful for gifts of small microscopes which any reader may be prepared to present to the Home.

THE Sir William White Post Graduate scholarship in naval architecture (1937) of the Institution of Naval Architects has been awarded to Mr. Allan M. Baxter, of the Royal Technical College, Glasgow.

THE following scholarships for 1937 have been awarded by the Institution of Electrical Engineers: Duddell Scholarship to R. S. Peacock, King's School, Ely; Swan Memorial Scholarship to Dr. B. C. Robinson, Armstrong College, Newcastle-on-Tyne; William Beedie Eason Scholarship to R. P. Kinsey of Evershed and Vignoles Ltd.; Silvanus Thompson Scholarship to J. R. Catlin, of Igranio Co. Ltd.; David Hughes Scholarship to L. Lieberman, Queen Mary College, London; Salomons Scholarship to S. G. Bittles, College of Technology, Belfast; War Thanksgiving Education and Research Fund (No. 1), Grant of £50 to J. E. Parton, University of Birmingham; Paul Scholarship to T. H. Fulford, Acton Technical College, London.

ERRATUM.—Dr. Gwyn Williams informs us that the MS. of his letter "Kinetics of Catalysed Polymerization of Styrene" (*NATURE*, Aug. 28, p. 363) contained an error. The polymers produced have molecular weights of the order 3,000, not 5,000 as printed (p. 364, col. 1, line 10).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 428.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Light thought to have been seen in the Neighbourhood of Alternate Current Magnets

THE late Prof. S. P. Thompson showed that visual effects (excitation of the optic nerve) were produced when the head was placed in an alternating magnetic field.¹ He said, further:

"Nearly four years ago Prof. Birkeland of Christiania told me that his workmen at the nitrate factory at Notodden declared that they could see lights over the choking coils used to limit the currents supplied to the electric furnaces. This may have been in reality a subjective phenomenon similar to that now recorded."

No doubt the view expressed by Prof. Thompson is the most probable. It seemed worth while, however, as a 'fool experiment', to see whether objective lights could be detected by prolonged photographic exposure.

Dr. W. H. Hatfield, to whom I casually mentioned the idea, was so kind as to interest himself in it, and he had a suitable alternate current magnet constructed at the Atlas and Norfolk Works, Sheffield. The iron was, of course, laminated, the gap between the poles being about 0.7 mm. wide and about 8 mm. deep. The mean flux density through the cycle was 4800 lines per sq. cm.

The top of the magnet was flat, so that a photographic plate could be brought right up to the gap, the lines of force being parallel to it. An Ilford hypersensitive panchromatic plate was used, with a thin sheet of 'Cellophane' between it and the magnet.

If the effect existed, there should have been a dark line on the plate, corresponding to the gap. Exposures up to thirty days were given, but no positive result was obtained. Some test experiments indicated that a luminosity fairly distributed through the visual spectrum and just bright enough to be seen by a well rested eye should have impressed the plate easily in twelve hours. The actual exposure was some sixty times greater. It appears most improbable, therefore, that any objective lights can exist. Perhaps most readers of NATURE would have been content to assume that in the first instance.

Cosmic Rays and Magnetic Storms

S. E. FORBUSH¹ has noted a systematic decrease of cosmic ray ionization at Cheltenham, U.S.A., and Huanacayo, Peru, simultaneous with a decrease of the earth's horizontal magnetic force (H.F.), during magnetic storms of April 1937. V. F. Hess and A. Demmelmair² have confirmed the existence and world-wide character of the cosmic ray decrease by

observations on the Hafelekarr near Innsbruck. They agree with Forbush in concluding that the study of these cosmic ray changes during magnetic storms will give valuable information on the spectrum of the cosmic radiation.

It promises also to settle an important unsolved question which bears closely on the mode of origin of magnetic storms themselves. The most intense disturbance of the earth's surface field during a magnetic storm usually occurs in polar regions; but this is not the part of the disturbance with which the greatest change in the energy of the magnetic field round the earth is associated. The energy change depends mainly on the general decrease of H.F. that occurs in all latitudes during and after the main phase of a magnetic storm³. The polar magnetic disturbance appears to be due to electric currents in the earth's atmosphere, but it is not known where the general decrease of H.F. is produced, except that the main cause is above the earth⁴. It may be in the highest layers of the ionosphere or right outside the atmosphere.

Ferraro and I have tentatively suggested⁵ that it may be due to a ring current encircling the earth at a radial distance of a few earth-radii, a , and composed of positive and negative charges in oppositely directed orbital motions. Störmer⁶ had earlier suggested a ring current of much larger radius, composed of charges of one sign only. I have criticized this hypothesis on various grounds^{7,8}, one being that it would imply an appreciable modification of the earth's field, during a storm, throughout an immense volume of surrounding space, in a manner likely to alter considerably the normal paths of cosmic rays. The present observations give a quantitative relation between the change in cosmic ray intensities and the magnitude δH of the decrease in H.F. at the equator during a storm; they should, with the aid of such calculations of cosmic ray paths as have been made by Störmer and by Lemaitre and Vallarta, lead to an estimate of the distance of the currents which reduce the H.F.

Below these currents the H.F. is reduced, above them it is increased, and there the main component of the earth's field corresponds to a doublet of magnetic moment $M + \delta M$ exceeding the earth's normal moment M . It is presumably this increase δM , in this outer space, which accounts for the decrease of cosmic ray intensities.

Theoretical discussion of the cosmic ray change might conveniently be based on the following simple model of the earth's field during a magnetic storm. It is not intended to represent all the important actual features of the field, even if the currents concerned are located in the high ionosphere, and still less if they are ring-currents outside; but it should give the order of magnitude of the radius a' at which the currents are located.

Take one third of the equatorial decrease of H.F. to be due to induced internal currents (having an equivalent magnetic moment $-\frac{1}{3}a^2\delta H$), and two thirds to be due to external currents. Take these to be distributed over a concentric spherical shell of radius a' , the current intensity being proportional to the cosine of the latitude; the field within the shell will be uniform, $-\frac{2}{3}\delta H$, and outside it will be that of the doublet of moment $+\frac{2}{3}a'^2\delta H$. Thus, for $r > a'$, the equivalent doublet of the total field will be $M + \delta M$, where $\delta M = \frac{1}{3}(2a'^2 - a^2)\delta H$. In this region the existing theory is applicable, with merely this change in M . For $a < r < a'$, the field will be that of a doublet $M - \frac{1}{3}a^2\delta H$ and a uniform field $-\frac{2}{3}\delta H$; in this region special calculations are needed. The important point is to determine whether a'/a is but little greater than unity, which would indicate that the currents are in the high ionosphere, or of magnitude 2, 3 or more, which would favour the ring-current hypothesis of the main phase of a magnetic storm.

The Cluster Theory of Imperfect Gases

DEVIATIONS from ideality of real gases are generally attributed to the effects of the volume of the molecules and to the attractive forces between them. The volume effect has been described fairly simply and accurately, but explanations put forward as to the way in which the attractive forces act are open to criticism. One of the older common explanations¹ is that the unbalanced attraction inwards on the molecules near the boundary wall results in their being slowed down before they hit the wall, thus giving a lower contribution to the pressure than they would in the absence of attractive forces. As stated, this appears to be a violation of the Principle of Equipartition of Energy. Another way of expressing what is probably the same thing, is often preferred². In this, the deficiency in pressure is attributed to a lower concentration in the boundary layer arising out of a relatively higher potential energy in this layer, due to the attraction inwards. These explanations ignore the fact that adsorption measurements show that all known walls exert a strong attractive force on all gaseous molecules and that the concentration in the boundary layer is invariably higher than that in the body of the gas.

Extensive mathematical treatments of the properties of imperfect gases have been made by Keesom³, Core⁴, and others⁵. These are based on the well-known statistical law that the probability of finding molecules in an element of volume dv is proportional to $e^{-X/RT}dv$, where X is the potential energy of the molecule. The treatment leads to the expected result that molecules are more likely to be found in an element of volume within the range of molecular attraction than in a volume outside this range.

It also gives values for the 'second virial coefficient' of gases, a coefficient to which $(b - \frac{a}{RT})$ of van der Waals' equation is in approximation.

Attempts at obtaining a kinetic picture of the above result lead to an interesting conclusion. Consider any molecule in a gas moving with a definite velocity. As it enters a region of lower potential energy such as occurs in the neighbourhood of another molecule its kinetic energy increases. During the whole of the period while it is in this region, except for the small fraction of time of actual collision, the molecule moves *faster* than before the collision. If this were the complete picture, molecules would spend *less* time in an element of volume within the range of molecular attraction. It might be argued that a consideration of all types of collisions would give a mean different from this. Calculations of a number of typical cases have, however, failed to reveal any exceptions. As an extreme example, overtaking and overtaken molecules spend a longer time than usual inside the range, but they would spend a still longer time inside the same volume if there were no attractive forces.

It is obvious from the above argument that molecules *normally avoid* elements of volume in the neighbourhood of attracting molecules, a fact that should give rise to a correction term of the same sign as the 'b' term of van der Waals' equation. The observed sign is, of course, the opposite. This can only be explained by assuming that a molecule, while in a range of low potential energy, sometimes loses part of its kinetic energy by collision with a third body, forming a stable 'cluster' with the other molecule. These clusters have a comparatively long life and more than compensate for the effect described above, giving a net result of the right sign. For complex molecules third body collisions are unnecessary, as the energy may be temporarily transferred to another degree of freedom of the system.

This phenomenon of stabilization is a general one entering into all kinds of equilibria involving fields of force. In the simple case of any molecule moving downwards in an isothermal box in a gravitational field, its velocity will increase and, in the absence of collisions, it will normally spend *less* time in the region of low potential energy. The Boltzmann distribution arises from the fact that a few molecules lose so much energy on collision with the walls that they are unable to rise to the top against the field, and spend therefore a much longer time at the bottom.

The existence of clusters has been postulated by many writers to explain their observations on various properties of real gases. Van der Waals⁶ himself believed them to exist near the critical point; he used the term *Scheinassoziation*. In the derivation of van der Waals' equation of state by Herzfeld and Smallwood⁷, the formation of clusters is realized. Volmer⁸ discusses the likelihood of molecular aggregates acting as condensation nuclei in pure super-saturated vapours. The possibilities in the Cluster Theory to explain the behaviour of gases have not, however, been generally realized and the theory is not to be found in elementary textbooks.

Tri- and tetra-molecular clusters are formed in a similar manner, particularly at higher pressures. At normal pressures, di-molecular clusters predominate, a fact which, with the Mass Law, leads at once to an equation of state of the type of van der Waals.

It is proposed to discuss elsewhere the ways in which the Cluster Theory permits simple treatments of other physical properties of gases, such as specific heat, viscosity, light scattering, the Joule-Thomson effect, and the pressure-broadening of spectral lines.

A Method of obtaining Polarized Neutron Beams

RECENT progress in cooling methods have made it possible to obtain temperatures where kT becomes comparable with the energy separation, due to space quantization of nuclear spins in high magnetic fields.¹ The nuclei will, under such conditions, occupy the lower levels of space quantization more abundantly than the higher ones, provided that temperature equilibrium between the lattice of the cooled substance and its nuclei is obtainable.² This effect is equivalent to a polarization of the nuclei, and might be useful for obtaining highly polarized neutron beams without great loss of intensity.

Should the nuclei in question have a resonance level for absorption of slow neutrons (thus absorption by an S -level) it would be expected that the capture cross-section would be very dependant on the relative orientation of the neutron spin and the spin of the capturing nucleus. In the special case of an unexcited nucleus having the spin $1/2$ and the compound nucleus—formed by slow neutron capture—the spin 0, the cross-section should be zero for neutrons the spin of which is parallel to the nuclear spin, whilst it should be normal for neutrons of opposite spin orientation. A substance the nuclei of which are polarized will thus polarize a beam of slow neutrons by selective absorption of one component of spin orientation. The degree of polarization will only depend on the ratio of occupation of the two levels of space quantization.

In the rare case of a group of thermal neutrons principally due to one nuclear resonance level, this method will furnish polarized beams of thermal neutrons, as the method proposed by F. Bloch.³ In most cases, however, only neutrons belonging to one particular resonance level—thus neutrons having energies of several volts—will be polarized. Precision experiments with such neutrons will permit of measurements of their velocity.

Added in proof: Halpern and Johnson⁴ point out that some paramagnetic salts could give higher magnetic scattering cross-sections for slow neutrons than iron, the atomic factor being bigger. At ordinary temperatures scattering of slow neutrons by paramagnetic salts will not furnish polarized neutron

beams. It might, however, be useful to employ for the polarization method proposed by F. Bloch³ paramagnetic salts magnetized at very low temperatures instead of magnetized iron.

Circular Ultra-sonic Grating in Liquids

A. Žáček and V. Petrůlka have recorded observations of radial and torsional vibrations of annular quartz plates cut perpendicular to the optical axis and have found that, with radial oscillations, standing ultra-sonic waves, which can be rendered visible by means of precipitated lycopodium, are formed in the hole in the middle of the crystal plate.

FIG. 1.

A closer investigation of the acoustic field showed that one was dealing with a complicated phenomenon, and that the ultra-sonic waves might be caused not only by radial vibrations but also by other types of vibrations, thus forming interesting figures of lycopodium. This fact was the reason for producing ultra-sonic waves in both gases and liquids, and observing them closely. These experiments have shown that the ultra-sonic waves formed in xylol, or better in a mixture of xylol and carbon tetrachloride, can be observed not only in the hole but also around the crystal plate. In the case of radial vibrations, only concentric circles are produced. If we make use of other types of vibrations, not only concentric circles, but also diametrical lines may appear (Fig. 1). This phenomenon is in all probability connected with the electrical axis of the quartz crystal. The circular grating formed in the liquids by the standing waves will be further utilized in diffraction experiments.

Vitamin E Deficiency in the Suckling Rat

It has been reported previously^{1,2} that partial deficiency of vitamin E in the doe rat leads to the production of abnormal young. This abnormality is associated with both anterior pituitary deficiency and thyroid deficiency. It is most marked when the litter is about eighteen days old and usually results in death three or four days later.

Since at birth the young, though small, appear otherwise normal, it seemed possible that the abnormality develops after birth and might be prevented if the young were fed by a normal doe. An E-deficient rat had a litter of three—two males and one female. Five days after birth, the two males were exchanged for four males from the normal breeding stock which were born on the same day. The stock mother then had her own females and the four normal males. All the young suckled by the E-deficient doe were abnormal at 16 days, and all were dead two days later. The thyroid glands were examined histologically and all showed the hypoplasia typical of this condition. All the young suckled by the normal rat grew well and showed no sign of abnormality. The experiment was repeated, with the same result, when the females from the two litters were exchanged on the fifth day, and again when the young were transferred on the day of birth.

This experiment shows that the young of vitamin E-deficient rats are born normal, but that thyroid and anterior pituitary deficiency develop as a result of the lack of some essential constituent of the mother's milk. This missing factor is almost undoubtedly vitamin E since lack of this vitamin results in similar changes in these glands in the adult rat, although the accompanying symptoms of stunted growth, uncalcified skull, clenched feet and weakness are not observed because the animal has already attained maturity.

Vitamin P

We have reported previously that certain flavanones (vitamin P) greatly influenced symptoms of experimental scurvy. This latter condition was interpreted as a mixed C and P avitaminosis. At our request, our experiments have been repeated by several laboratories. The results were partly corroborative and partly negative. The reason of this discrepancy is now cleared up. Vitamin P requires for its activity the presence of traces of ascorbic acid. A scurvy diet frequently contains such traces which in themselves have no influence on the development of scurvy, but enable vitamin P to act. In the entire absence of ascorbic acid, vitamin P is inactive. Quantitative data will be published elsewhere. Previous conclusions are upheld. The object of this note is to prevent superfluous discussion.

Choline Esterase Activity of Superior Cervical Ganglia

By a direct chemical micro method the maximum choline esterase activity of the superior cervical ganglion of the cat has been measured and found to be, on the average, equivalent to the splitting of 0.10 γ of acetylcholine chloride per sec. per mgm. of fresh tissue. The full experimental details will be given in another publication.

This figure may be applied to the data of Brown and Feldberg¹, who found that the greatest output of acetylcholine from the ganglion perfused with egerinized Locke's solution occurs in the first 5 minutes of preganglionic stimulation at 17 per sec. In this time 0.1 γ was liberated from a ganglion weighing 12.9 mgm. Hence the time required for the splitting of the acetylcholine liberated by one nerve impulse would be

$$\frac{0.1 \gamma}{12.9 \text{ mgm} \times (0.10 \times 10^{-3} \gamma/\text{mgm} \cdot \sigma) \times (300 \times 17) \text{ stimulations}} \\ = 0.015 \frac{\sigma}{\text{stimulation}};$$

provided that the enzyme and substrate are localized sufficiently so as to obtain a complete combination of the two, that is, theoretical maximum velocity of hydrolysis. Actually, the velocity falls when the concentration becomes less than a certain value; hence 0.015 σ represents a limiting least time which might be merely approached in actuality. Compared to the refractory period of the ganglion, which Brown² has found to be of the order of 2 σ , it is apparent that the enzyme need operate only with an average rate of about 0.75 per cent of its theoretical maximum velocity in order to destroy the acetylcholine liberated by a nerve impulse within the refractory period. After the first 5 minutes, the quantity of acetylcholine liberated per impulse falls until finally only about a fifth of the initial amount is set free¹; under these conditions the enzyme could hydrolyse the acetylcholine within the refractory period at about 0.15 per cent of its maximum velocity.

From the foregoing it would appear that the enzyme present is sufficient to destroy the acetylcholine liberated by a nerve impulse within the refractory period. However, it must be borne in mind that for the conditions of minimum velocity of hydrolysis, as in the case of an even distribution of enzyme and substrate throughout the tissue, the reaction velocity would be very far indeed from the maximum one, because of the low substrate concentration and affinity for the enzyme. In this case the time (t_s) for splitting 99 per cent of the substrate is given by:

$$t_s = \frac{1}{V_{\max}} \int_{S_1}^{S_2} \frac{K_s + S}{S} dS,$$

where $V_{\max}$ represents maximum velocity of hydrolysis, K_s the Michaelis constant for the affinity between enzyme and substrate, S the substrate concentration at any moment, S_2 the original substrate concentration, and S_1 1 per cent of S_2 . It follows that:

$$t_s = \frac{1}{V_{\max}} (K_s \ln \frac{S_2}{S_1} + S_2 - S_1) = \frac{4.6K_s + 0.99S_2}{V_{\max}}.$$

Since the value of K_s , which I am now investigating, is unknown for the enzyme from the source in question, it is sufficient for a rough calculation to assume it to be of the same order of magnitude as the K_s already found in the case of human serum³, namely, 0.001, from which t_s becomes about 8 sec.

In order that this time be reduced to 2 σ , it would be necessary for the enzyme and substrate to be concentrated within a small portion of the total ganglionic volume, such as at the nerve endings. Already evidence for a localization of this type has accumulated^{4,5}.

The calculation given above is merely an approximation, and serves only to show the enormous gap between the time for splitting under minimum and maximum conditions, and the necessity for localization of enzyme and substrate within the ganglion cell if the theory of chemical mediation is to hold.

Choline Esterase in the Central Nervous System

THE theory of transmission of nervous impulses to the voluntary muscles postulates the presence of a high concentration of choline esterase in nerve endings or their neighbourhood¹. We have previously demonstrated the accumulation of choline esterase at the end plates of muscle². We have now compared the rate of hydrolysis of acetylcholine in the grey and white matter of the spinal cord of the dog and found the concentration 10-20 times higher in the grey matter. 100 mgm. grey matter hydrolyses 7-9 mgm. acetylcholine in one hour, while 100 mgm. white matter split only 0.4-0.9 mgm.

In the central nervous system, as in muscle, choline esterase is found in high concentration in the tissue that contains nerve endings. This suggests that in the grey matter the enzyme may have a similar functional significance as at the end plates of muscle, that is, the rapid removal of acetylcholine, and that this substance may act as transmitter of nervous impulses in the central nervous system.

In the nervous system of crustaceans (lobster) there is also a higher concentration of choline esterase in the ganglion cells than in the nerve fibre.

Specificity of the Salicylic Aldehyde Reaction of Csonka-Straub

SOME time ago Straub (in Szent-Györgyi's laboratory) described a colorimetric method for the determination of pyruvic acid, similar to the method previously proposed by Csonka for the determination of acetone. In the presence of salicylic aldehyde and concentrated potassium hydroxide, both substances develop a yellow colour, suitable for colorimetry. Having met with the necessity of determining pyruvic acid in the presence of several other ketones, I have made a study of the specificity range of this reaction and obtained the following results.

A positive salicylic aldehyde reaction is obtained with all compounds containing a CH_2CO group linked directly to a hydrogen or carbon atom; for example, acetaldehyde, acetone, ethyl acetoacetate, methylhexylketone, diaetyl, acetophenone, pyruvic acid, levulinic acid. The reaction is negative: (1) with carbonyl compounds that do not contain the above-mentioned group—formaldehyde, propionic aldehyde and higher homologues, ketobutyric acid and all higher ketosacids, fructose, dihydroxyacetone, acetonedicarboxylic acid; (2) with compounds containing a CH_2CO group linked to oxygen or nitrogen, that is O- and N-acetyl compounds, the CO group of which is not a genuine carbonyl group; for example, acetic acid, acetyl glycine, acetylcholine, acetylsalicylic acid, triacetin.

The mechanism responsible for this very definite range of reaction specificity is obviously the following. In the first stage of the reaction salicylic aldehyde is condensed with the carbonyl compound to an oxybenzylidene derivative (Perkins' reaction):

If a menthyl group be attached to the carbonyl group of the original compound, that is, in the case $\text{R} = \text{H}$, enolization will ensue in a strongly alkaline medium, leading to the formation of an enolate, the intense yellow colour of which is due to the system of cumulated double bonds:

With R other than a hydrogen atom enolization and the formation of the cumulated double bond system is ruled out and no colour will appear, even though benzylidene condensation had taken place. With O- and N-acetyl compounds neither the condensation nor the enolization is obtained under the conditions of the colour test.

The salicylic aldehyde reaction is a sensitive test for the qualitative (and in many instances for the quantitative) determination of any methyl-carbonyl-derivative in the absence of other substances belonging to the same group. The reaction is very important as a valuable means for distinguishing these compounds from the homologous or substituted carbonyl derivatives. The specificity range outlined above should be especially kept in mind when making use of the reaction for quantitative studies on the metabolism of pyruvic acid, which may give rise to substances such as acetaldehyde, acetoin, acetoacetic and acetylpyruvic acids and acetone, all falling within the specificity range of the Csonka-Straub reaction.

A Cage Colony of *Anopheles gambiae* Giles

MATHIS¹ has reported the successful rearing of *A. gambiae* under laboratory conditions. He fed the adults on a guinea pig and found that mating occurred in quite small cages. For some years now I have made attempts to establish a laboratory colony of this species without any success. Great difficulty has always been experienced in getting caged adults to feed. The following animals have been tried: shaved guinea pigs, rabbits, goats and human beings. When feeding did take place, no fertilized eggs were recovered. Recently a further attempt has been made, and this has proved successful.

Adult *gambiae* reared from eggs, obtained from gravid females captured in the field, were placed in an indoor cage lined with asbestos measuring 6 ft. x 5 ft. x 5 ft. The temperature in the cage was kept constant at 25° C. by means of a radiator connected to a thermostat. Large bird-baths and ferns were placed inside, yet the humidity of the air in the cage, as measured by a sling hygrometer, never rose above 40 per cent.

For a month the insects were given the opportunity of feeding on a human being every evening, and they very seldom took advantage of this. At the end of this period, however, nearly full-grown larvae were seen in one of the bird baths and very robust adults resulted.

After this date a small pig was introduced and the mosquitoes fed very readily. Eight days after introduction of the pig, first-stage larvae were seen in the breeding dishes; these represented the second

generation in captivity. Since that date hundreds of larvae have appeared and third generation adults are now ready to deposit eggs. The colony is regarded as being firmly established.

The Position of Genetics

THE attacks of Lysenko on Vavilov and other Russian geneticists reported in *NATURE* of August 21 are not wholly dissimilar to Dr. H. Dingle's attack on Prof. E. A. Milne in a recent issue of this journal. Vavilov was accused of being anti-Darwinian, Milne of going back to Aristotle, in neither case perhaps with full justification. If these attacks have led to a curtailment of Vavilov's work, the situation of genetics in the Soviet Union is indeed serious. If not, hard words break no bones, and the outlook for genetics in Moscow is at any rate no worse than in London, where I understand that the only department of genetics in the University is shortly to come to an end.

Points from Foregoing Letters

LORD RAYLEIGH has made photographic tests to see whether, as had been supposed by certain observers, there were lights in the field of an alternate current magnet. The result was negative.

Prof. S. Chapman indicates that the decrease of cosmic ray intensity noted by Forbush in America (United States and Peru) and by Hess and Demmelmair in Austria, during the magnetic storms of April 1937, should throw light on the mechanism of magnetic storms; in particular, it should show whether the world-wide decrease of horizontal magnetic intensity during a magnetic storm is due to currents in the high ionosphere or to a ring-current right outside the earth's atmosphere.

The 'cluster' theory, which postulates that the molecules of imperfect gases occur in groups (mainly pairs under ordinary conditions), permits, according to C. F. Goodeve, a simple treatment of many properties of imperfect gases.

The possibility of obtaining polarized beams of neutrons by selective absorption on passing through a substance cooled to very low temperatures, the nuclei of which have a resonance level for absorption of slow neutrons, is pointed out by Dr. Hans v. Halban, jun. Paramagnetic salts magnetized at low temperatures might be employed for this purpose.

Standing ultra-sonic waves produced in xylol, or in a mixture of xylol and carbon tetrachloride, by an annular quartz plate can be observed within the ring and also outside the crystal plate. Miss J. Čerňavská submits a photograph obtained with radial vibrations, showing that a concentric circular grating has been formed in the liquid; this can be used in diffraction experiments.

Further experiments by Miss M. M. O. Barrie show that the young of vitamin E deficient rats are born normal but that they develop symptoms connected with thyroid and anterior pituitary insufficiency. However, if suckled by a normal rat, the young develop normally, showing that there is a lack of some essential constituent (probably vitamin E) in the mother's milk.

By a micro-chemical method D. Glick has calculated the rate at which choline esterase enzyme, acting on the super cervical ganglion of the cat, can split acetylcholine, a compound liberated during nerve activity. The time required is well within the refractory period of the nerve impulse, provided the known amount of enzyme and substrate are concentrated at the nerve endings. D. Nachmansohn has found an increased concentration of choline esterase at the nerve and plates of muscles and now reports that the grey matter of the spinal cord of the dog contains 10-20 times more choline esterase than the white matter. He suggests that the grey matter may act as transmitter of nervous impulses in the central nervous system.

The salicylic aldehyde reaction which gives a yellow colour with acetone and pyruvic acid (Caonka-Straub) is found by Prof. A. E. Braunstein to be a sensitive reaction for any methyl-carbonyl (CH_3CO) derivative, in the absence of other substances of the same group. The author directs attention to the fact that, in studying the metabolism of pyruvic acid, one should be on the look-out for substances such as acetaldehyde, acetoin, acetoacetic and acetopyruvic acids and acetone, which also give the Caonka-Straub reaction.

Research Items

Clan Reciprocity among the Bororo

IN an account of the social organization of the Bororo Indians of South America, M. Cl. Levi-Strauss refers to certain reciprocal obligations between clans, which he considers worthy of intensive study. He himself was able only to obtain a few discursive notes on the customs this reciprocity entails (*J. Soc. Américanistes de Paris*, N.S., 28, 2). For example, when the young men are about to be initiated, the chief of the village entrusts their instruction to the phratry opposite to their own. On the death of a member of the tribe, it is customary for a collective hunt to be arranged. The organization of the hunt is entrusted by the nearest relative of the deceased to a member of the opposite phratry. The funeral emblems are handed to him, and he acts as organizer and leader. The preparation for the funerary dances is the duty of special clans; but the clan for whom the dance is prepared must take part as partners. This duality is well expressed in certain dances, in which the dancers stand in two lines and exchange places in the course of the dance. Each line or side belongs exclusively to one phratry. After the dance, the dancers are bathed by the members of the opposite phratry. An even closer tie binding the clans is formed by the interchange of food. At a stated time a member of one of the clans will carry a bowl of food from his own house to the man's house, where it is received with a ritual cry of welcome. Six or eight men of another clan are then fetched to the man's house, and partake of the food with their shell spoons. This exchange of food takes place reciprocally between all the clans, though with the exception of this ceremony and the giving of food to dancers after the dance, all meals are taken in the family dwelling. The privileges of the clans include the exclusive possession of names, songs, dances, and emblems and of certain techniques and materials. These rights are strictly respected.

The Human Sex Chromosomes

FROM a study of spermatogenesis in three individuals, Dr. P. C. Koller (*Proc. Roy. Soc. Edin.*, 57, 194) has deduced some interesting conclusions. The length of the X-chromosome in man is found to be 4-5 μ and that of the Y 1.5 μ . These chromosomes frequently lie off the metaphase plate in mitosis, and in anaphase the Y frequently lags. In the leptoxgotene stages of meiosis the X and Y are precociously condensed. They are divided into pairing and non-pairing regions. The non-pairing portion of the X is about two thirds of its length, while that of the Y, if present, is very small. The spindle attachment of the X is subterminal and is believed to lie in the pairing segment, so that crossing-over may occur on either side of it. The region between the centromere and the non-pairing (differential) segment is a quarter to a half that of the whole pairing region in which crossing-over will take place. Genes in this part of the X will show incomplete sex linkage, the linkage being lowest in loci farthest from the non-pairing segment. Both symmetrical and asymmetrical sex bivalents were found, and the X and Y sometimes fail to pair. In one individual

chromatid bridges and fragments were observed. He was probably heterozygous for an inversion. Such inversions may yet prove to be of significance in the racial differentiation of man.

Barbels of Japanese Fish

THE structure and function of the barbels of two Japanese fish have been investigated by Mitus Sato (*Sci. Rep., Tôhoku Imp. Univ.*, Feb. 1937, 3 papers). One, the goatfish, *Upeneoides benesasi*, has two long barbels on the chin, and the other, a sea catfish, *Plotosus anguillaris*, has four pairs of barbels, two pairs above and two below the mouth. The barbels in both fish have a central supporting cartilaginous rod and in the epidermis covering them lie a number of characteristic taste organs which are supplied by branches of the fifth and seventh cranial nerves. In the catfish such organs are also to be found in the lips. These organs are more important than either sight or smell in the selection of food. In the goatfish the removal of the barbels causes a loss of the power to distinguish food. This does not occur in the catfish, since some of the organs are left in and around the lips.

Chromosomes of Coffee Plants

A STUDY of the chromosomes of *Coffea* has been made by Dr. C. A. Krug (*J. Genetics*, 34, No. 3), who confirms that $2n = 22$ in *Coffea arabica* and has found the same number in seven other species. Most of the cultivated varieties of *C. arabica*, however, are tetraploids; while the var. *bullata* of Cramer, which has broader and much thicker leaves, is an auto-octoploid ($2n = 88$) or in certain plants hexaploid. The octoploid condition also arises somatically on a branch of a tetraploid, and can revert somatically to the tetraploid. Hexaploids are much less frequent, so it is concluded that the octoploids probably arise through chromosome doubling after fertilization. Their fruits are abnormal, giving a very low percentage of germination. All the offspring were $4n$ except one $6n$ and one $8n$. The $4n$ plants may have arisen parthenogenetically. The pollen meiosis in the octoploids is irregular, only about 62 per cent of the tetrads having four microspores. From $4n \times 8n$ seven plants were obtained, all having $2n = 44$. These must have arisen from parthenogenesis or by the fertilization of $2n$ eggs by $2n$ pollen. The hexaploids also show high gametic sterility and low seed production. Four seedlings were produced, three of which had 66 chromosomes and one 44. In reciprocal crosses between *C. arabica* ($2n = 44$) and *C. canephora* ($2n = 22$) a triploid hybrid plant produced misshapen seeds with little or no perisperm but with normal embryo. *C. canephora* has several chromosomes longer than the rest, and these are recognizable in the hybrid.

Petrofabric Study of Moine Schists

AT the meeting of the Geological Society on May 5, F. C. Cole presented an important paper dealing, for the first time, with the application of petrofabric analysis to the problems of the metamorphic rocks

of the Highlands. In all, 85 analyses of quartz and mica fabrics of Moine schists have been made. Specimens collected over a wide area have given in every instance a well-marked girdle-diagram, indicating that the schists are typical *B*-tectonites. In these, the direction normal to a girdle, known as the *b*-axis or tectonic axis, has the same significance as a visible fold-axis. The *b*-axes of the Moine pitch uniformly into the south-east quadrant, suggesting that the present regional metamorphic condition of the Moine is the result of movements along approximately south-west and north-east lines. The effect of the post-Cambrian overthrusting on the fabric of the schists is also examined. Relics of the earlier fabric are traceable in partially mylonized rocks, but the thrust movements have had little or no constructive effect, being in the main cataclastic, and the continuity of the structure is lost. The evidence indicates that the general metamorphism of the Moine schists was effected by movements, earlier than the overthrusting phase of the Caledonian orogeny, acting in a direction almost at right angles to the direction of overthrusting, but parallel to pre-Torridonian directions of movement in Lewisian areas.

Drilling of a Deep Pressure Test in India

EXPERIENCE has shown that problems pertaining to the drilling of a well under pressure to great depth are many and formidable. The main difficulties to be overcome are shallow zones of low-pressure sands, which cause loss of fluid and circulation, deeper high-pressure water and gas sands, 'heaving shale' formations and hard formations, which retard drilling and are conducive to crooked holes. Mr. G. F. Wilson, in a paper presented to the Burma Branch of the Institution of Petroleum Technologists on May 4, described measures which have been adopted to overcome these particular difficulties when drilling a deep well in India. The casing was set below the low-pressure zone; heavy mud was used as well as pressure drilling; by continuous maintenance of pressure and the use of treated muds, heaving shale formations were penetrated and the effect of hard formations counteracted so far as possible by provision of a hydraulic table. The history of this test well showed that pressure drilling is quite practicable for prolonged periods, providing the best obtainable equipment is used. Where, however, rock pressures are known and can be dealt with by mud, it is better not to employ pressure drilling, but to keep it as a standby, since the increased cost of fuel and equipment for drilling under pressure is in most cases greater than that of mud-loading materials.

Crystalline Structure of Pentaerythritol

THE elucidation of the structure of sugars by X-ray analysis has been hampered by lack of knowledge of various interatomic distances. F. J. Llewellyn, B. G. Cox and T. H. Goodwin (*J. Chem. Soc.*, 883; 1937) have made an analysis of the relatively simple compound pentaerythritol, $C(OH)_4$, which shows that the model consists of a central carbon atom surrounded by four CH_2 groups at the corners of an almost exact tetrahedron; each hydroxyl group is attached to its CH_2 by a bond making nearly a tetrahedral angle with the $C-CH_2$ link, and is so directed that the four OH groups lie at the corners of a square. The bond lengths and angles were

calculated from the measured atomic co-ordinates and cell dimensions, the distances being $C-C=1.50$ Å. and $C-O=1.46$ Å., the first being slightly less than that found in diamond and usually assumed for aliphatic compounds, and the second almost exactly equal to the calculated sum of the half-bond lengths of carbon and oxygen. The structure of the lattice as a whole is of a very pronounced layer type, the molecules being linked together by hydroxyl bonds in sheets in the (002) planes, and the separation of more than $3\frac{1}{2}$ Å. accounting for the perfect cleavage parallel to {001}. The evidence supports the view that the relatively short distance between hydroxyl groups represents a hydroxyl bond in which a hydrogen atom binds two oxygen atoms closely together while remaining attached essentially to one of them. The arrangement is very similar to that found in resorcinol. All other inter-molecular distances are much greater and correspond with relatively weak van der Waals' forces.

Determination of Lactoflavin in Milk

A RAPID method for the determination of lactoflavin (vitamin G) in milk by a fluorimetric method is described by C. H. Whitnah, B. L. Kuerth and M. M. Kramer (*J. Amer. Chem. Soc.*, 59, 1153; 1937). To 10 ml. of milk, 16 ml. of 10 per cent trichloroacetic acid is added, the mixture is allowed to stand for $\frac{1}{2}$ -1 hour and centrifuged for 5 minutes at 2,000 r.c.f. Ten ml. of the resulting serum is neutralized with methyl orange as indicator and diluted until the sample can be matched in the light of an Eberhard Fluoray lamp with standard flavin solutions (Labco PX grade) containing 0.12-0.06 gamma of flavin per ml. The consistency of the method was confirmed, and comparisons with the biological assay by the Bourquin-Sherman method were satisfactory. Attempts are being made to apply the method to colostrum, which is higher in lactoflavin content than normal milk.

Classification of Stellar Spectra

THE spectral classification of stars of types A to K has recently been discussed by W. W. Morgan (*Astrophys. J.*, 85, 380), who points out the desirability of a two-dimensional system of classification depending on effective temperature and luminosity. The system should be in empirical units based on the actual observed criteria in the spectra, so that no errors are introduced by assumptions involved in reducing these to values of the corresponding physical parameters. The Henry Draper notation provides a suitable method of classification in the temperature direction which is practically constant for all values of the surface gravity in the stars considered; but the criteria on which it is based should be as far as possible independent of a star's luminosity. Classification in the luminosity direction should similarly be based on lines which are unaffected by temperature over the range in which they are employed. The author suggests, as simple criteria which fulfil these conditions, some single line intensities, intensity ratios and differences. They enable the H.D. type to be determined with high accuracy, and (for types A7 to K9) give an additional numerical classification directly related to luminosity. The criteria for types A0 to A6 are not sufficiently accurate to give more than a 'group' classification (for luminosity) into super-giants, main sequence stars and white dwarfs.

The Bone-Bearing Beds of Bethlehem: Their Fauna and Industry

By Elinor W. Gardner and Dorothea M. A. Bate

IN a note in 1934 (*NATURE*, Aug. 11, 1934, p. 219) one of us (D. M. A. B.) directed attention to an interesting discovery of elephant remains in a deposit at Bethlehem. This was the result of a cursory examination on the spot undertaken for the Department of Antiquities.

Shortly afterwards, the late Sir Henry Wellecome became interested in the site, and a concession was obtained by Mr. J. L. Starkey from the Department of Antiquities, Palestine, for the Wellecome Archaeological Research Expedition to the Near East. In the spring of 1935 the Geological Section of the above Expedition began its first season's work with E. W. Gardner as geologist and D. M. A. Bate as palaeontologist. It was continued in 1936 under the same auspices, and resumed in 1937, thanks to the enthusiastic support of the trustees of the late Sir Henry Wellecome and of Sir Robert Mond.

GEOLOGY

The bones were first found by the owner of a garden digging for water on the highest point of Bethlehem, 790 m. above sea-level. On all sides the ground falls away, on the east towards the Dead Sea Rift, on the west towards the Mediterranean.

The position of the deposit isolated on the highest part of the Judean arch at once, therefore, aroused interest, for the solution of the problem of its origin would certainly throw interesting light on the past physiography of the region and its relation with the Rift Valley and Transjordan.

In the original pit, elephant bones were seen *in situ* at 15 m. below the surface. On opening up the area they were found some 6 m. down in a coarse gravel with a stiff clay matrix, which makes their extraction a slow and difficult business. The gravel consists mainly of chert of all sizes, some blocks being half a metre or more big. Limestone is a minor constituent, but is locally abundant. A few iron nodules are also found. The materials are very little sorted, and are mostly derived from local Cretaceous rocks, with the exception of the iron nodules, which are more characteristic of the Eocene.

As the excavation was enlarged it seemed in the first season as though there were two gravels separated by a bed of pure clay, all dipping east, but later work showed that in depth the two gravels coalesce. They are both bone-bearing, in contrast to the pure clay, which has never yet yielded any remains.

Those in the western gravel are badly preserved, perhaps because they occur nearer the surface and are less protected by deposit of lime or nari towards the top. An interesting specimen found there was a

jaw of an elephant, and perhaps part of the skeleton. The mass of bone, 3 m. long, dipped, with the beds, steeply to the north-east; while some of the deposits in the north-east corner—the original area—dip as steeply ($\pm 40^\circ$) to the south.

In 1935 no junction of the gravels and clays with country rock was found, and therefore in 1936 the area was enlarged in the hopes of finding one.

On the east and south a white chalky rock, nari with humps of limestone, had already been sporadically uncovered, and on cutting back the south side it increased rapidly both vertically and laterally. In places it arches over the gravel, sometimes with a

Fig. 1.

very clean junction. It is veined with red clay, which in places develops into pipes narrowing upward, and mostly dipping eastward. In depth blocks of limestone, some with fossils, become more and more abundant and of increasing size. The surface of these is weathered sub-aerially, and often shows characteristic carving and fretting.

The gravel in the west lies on this deposit, which may be called a cemented scree or breccia, at a steep angle, and sometimes penetrates into it as pipes. The approach of the scree is heralded by increasing numbers of limestone boulders in the gravel and by the reddening of the clay. In the east and south-east, on the other hand, the junction is sharp and vertical, or nearly so, the gravel and clay fall away under the pick in big masses, leaving a clean face of white rock. In the same area vertical or steep clay faces are exposed in the same way, and these, if not on the junction, are always very near it.

On the south the steep scree face has been followed down for 11 m., at which depth it flattens out into a small platform before plunging down again. From the northern edge of this platform a hard triangular mass of breccia rises two metres above the floor. The space between it and the southern wall was filled

with grey bone-bearing gravelly clay, which ended quite abruptly against the breccia block. A somewhat similar but smaller mass has been found in the north-west corner. The irregularity of the surface of the scree deposit, together with the nature of the junction with the bone-bearing beds, seems to indicate that it was formed before them and that they were laid down on and against it.

In the south-east corner yet another curious deposit was found. This consisted of a pipe—3 m. broad—in the sand, and scree, filled with blocks of chert of all sizes, some more than a metre in all dimensions. In contrast to the chert in the gravel, which is more or less worn, these blocks of whatever size are sharply angular.

The pipe slopes in the north-east and ends some 6 m. down after narrowing slightly, and finally disappears in the narrow cracks of the cemented scree. On the south side of the pipe near the base the scree contained some remarkable polished cherts. They were found in pockets of red clay in the scree and were mixed with quite unworn and angular fragments. The polish is so high that it is more like a glaze. In some cases the cherts are intensively worn, in others and more frequently, they are less so and show numerous flake scars.

It is still too soon to discuss the origin of all these materials, but there can be little doubt that the gravel and clay bone-bearing series is a water-laid deposit, and that the bed against which it rests is a sub-aerial one.

The gravels are rapidly contracting in area as they go down and this, in conjunction with the inward dip, points to the filling of a roughly funnel-shaped hole, or alternatively to the collapse of the original floor on which they were laid. Whatever may be the ultimate decision, the impossibility of any such deposit forming in its present position indicates wide physiographic changes, which in their turn point to a great age. More exact dating must be left to the paleontologist.

ARCHAEOLOGY

It is possible, however, that some help in the dating problem may be obtained from implements. Throughout the work a close watch has been kept for human worked flints, but until this year nothing definite was found. Now, however, a number of possible tools have been obtained, in the bone-bearing gravel, and these, if accepted, will be invaluable not only in dating, but also in helping to trace the deposits elsewhere.

Miss Caton-Thompson, who saw them *in situ*, and has kindly consented to work them out, contributes the following note:

"The cherts in the deposit have a wide variation in size, ranging from huge blocks to small chips and pebbles. Both tabular and nodular varieties are present. The former is mainly represented by a pale greenish chalcodonic chert with a rough or corrugated cortex; the latter by a dark grey-to-black 'chalk flint'. A peculiar local variety, favoured on certain sites by Acheulean man for hand axes, is also included; it has the appearance of an angular pudding-stone, and is known as brecciated chert.

"The play of mechanical forces on the flints is strikingly evident. Striations, shattering, bruising, crushing, rolling and thermal action are all visible. Taken as a whole, however, rolling is very slight compared with normal gravel constituents, and a

considerable proportion of the material is relatively fresh.

"The danger of claiming humanly-fashioned tools from such an assemblage and so vast a selection is obvious. Nevertheless, we think that a certain number of pieces are difficult to explain in other terms. They will provoke healthy controversy as acute as that which has beset the 'artefacts' from the Red Crag of Foxhall, or the sub-Crag detritus bed flints at Bramford. Many of the Bethlehem 'artefacts' resemble the latter, in so far as both, when of tabular flint, conform closely in shape and edge trimming to the classic type of Harrisonian eolith. This is the first time they have been found in a sealed deposit in Palestine or the Near East, though Mr. Starkey has long known them from the bed of Wadi Ghuzzah. Flakes, though rarer, are also present, and display 'striking platform' and/or bulb.

"Balancing the probabilities, we think the type of flaking and edge trimming exhibited on these admittedly selected specimens is less easily reasonably to explain as the accidental work of natural forces, than as the deliberate experimental work of man in remote pre-Chellean times." E.W.G.

PALEONTOLOGY

The first discovery of fossil elephant remains in Palestine was announced in NATURE of August 11, 1934, p. 219. Subsequent finds have been made in the Wady Mughara caves and in the bed of the River Jordan not far from its exit from Lake Huleh, but both these are of later date than the deposit at Bethlehem which yielded the first remains. In fact, with the possible exception of a single specimen which I hope to describe shortly, the Bethlehem deposit has yielded a mammalian fauna of earlier geological age than any so far known from Palestine. As yet it has been possible to make only a preliminary examination of the animal remains obtained during the three seasons' work; this has revealed the presence of the following vertebrates:

<i>Felis</i> sp. (size of <i>Panthera leo</i>)	<i>Rhinoceros</i> cf. <i>strucosus</i>
<i>Hippopotamus</i> sp.	<i>Stegodon</i> sp.
<i>Bos</i> sp.	<i>Elephas</i> sp.
Antelope	<i>Testudo</i> sp. (of gigantic size)
Giraffoid	<i>Testudo</i> sp. (of very small size)
<i>Hipparion</i> sp.	

Besides the above species there is known to be a small carnivore, but its remains are extremely fragile and have not yet been extracted from the matrix. With, perhaps, the exception of the large *Felis*, the *Bos* and the tiny tortoise, all these species are new to Palestine, and without doubt represent extinct forms.

Among the mammals the name *Bos* is used in a broad sense, since the species is known only from portions of horn cores. Likewise the antelope and the Giraffoid are only represented by a small number of skeletal remains. The discovery of *Hipparion* is of special interest, both chronologically and geographically. Species are known from many Tertiary deposits in Asia, including India, and are generally considered to be typical of the Pliocene. Last year (1936) Father Teilhard de Chardin and Prof. de Terra recorded *Hipparion* remains from the Basal Pleistocene of India, although they themselves did not wish to claim this dating as proved conclusively. The find at Bethlehem seems to suggest that further corroboration may be forthcoming from India. In

East Africa, on the other hand, *Hipparion* remains are well known from Pleistocene deposits, and have been recorded from Oldoway, Beds I-IV, from Kaiso and from Lake Rudolf.

The Bethlehem *Rhinoceros* has been compared with *R. etruscus*, since some of the upper cheek teeth appear to be similar; the height of the crowns is, if anything, slightly less in the Palestine specimens. In this connexion it is of interest to remember that the late Dr. W. D. Matthew compared the Indian *Dicerorhinus platyrhinus* with *R. etruscus*.

The discovery of the *Stegodon* remains is of outstanding moment. This is essentially an Asiatic genus, though Dr. A. T. Hopwood allows me to mention that its occurrence in African deposits is now known and will shortly be published. India during the Pliocene appears to have been the great centre for the adaptive radiation of the *Stegodon* group. Here the genus lingered on into the Middle Pleistocene; in Java it is known from an even later horizon. As might be expected, the *Elephas* from Bethlehem is represented by a primitive form with low-crowned cheek-teeth.

The gigantic tortoise is known from a considerable number of plates from the bony carapace and plastron. Most of these were collected early this year and have not yet been examined critically. It will be remembered that remains of a gigantic tortoise were discovered by Dr. Leakey in East Africa in 1935.

Many of the animal remains have been subjected to pressure, and this corroborates the geological evidence that movements must have taken place after their inclusion in the deposit. Frequently it has seemed evident that complete carcasses have been embedded in the deposit, notably in the case of the elephant quoted above by Miss Gardner. Likewise it may be mentioned that so far the animal remains have given no indication of a difference of fauna from different parts of the excavation.

Unfortunately, owing to local conditions, specimens are generally very fragile, and always difficult to extract. It is hoped, however, that further work next spring may result in the acquisition of still larger collections, which will enable us to extend our knowledge of this new fauna.

In conclusion, it is suggested for the Bethlehem fauna that its origin is Asiatic, and that its age is not later than Early Pleistocene, using this term paleontologically as indicating the time of arrival of true *Bos*, *Elephas*, and *Equus*. The fauna also indicate a warm climate, with a more liberal supply of permanent water than is found in the country at the present day. Further, it is claimed for this fauna that it will provide a faunistic link for this period between Asia and East Africa, enabling a better understanding to be reached regarding the migrations and centres of dispersal of various mammalian groups.

The Lake District as a National Park

THE question of the afforestation projects which are being carried out by the Forestry Commissioners has been the subject of considerable controversy and alarm among residents of the Lake District and those who have an admiration for this beautiful piece of England.

The Friends of the Lake District have recently published a pamphlet entitled "Make the Lake District a National Park" (Ambleside: Friends of the Lake District. Sec., 2 Midland Bank Chambers, 1937), which is, in effect, an appeal to all lovers of the Lake District based on a new method of treating and preserving this unique region without involving any of the upset to local agricultural methods which is one of the strong objections offered to the Forestry Commission's activities. The pamphlet opens with the sentence, "Regions of great natural beauty have a lasting value for the refreshment and inspiration of man." The object of the proposal to create the area a national park is to preserve for the future the outward aspect of the district as at present seen "with the grand and the beautiful in splendid harmony". The formation of a national park does not necessarily entail the nationalization of ownership. "The policy has no quarrel with the essentials of the present system of land holding, or with the enjoyment of private property as such. It can be achieved inside the traditional framework."

One of the great objections to the afforestation proposals of the Forestry Commission has been the disturbance involved to local methods of agriculture, and especially to the famous strain of Herdwick sheep. The fells of the Lake District are rough grazing, occupied by Herdwick sheep; and, since

there is no conflict of interest between sheep and the pedestrian, the local agricultural system and free access, it is said, are good partners.

The valley bottoms are not arable, but grass land with a generous lay-out of footpaths on the 'inside land'; the meadows do not run far up into the dale-heads, nor do the 'intakes' run far up on to the hill-sides. The whole configuration and covering of the land is, given moderately free access, ideal for the formation of a national park. The tourist industry, second in importance only to the sheep, will greatly benefit and thus assist the local hardy inhabitants to enjoy a greater prosperity.

The Lake District extends over parts of the three counties of Lancashire, Westmorland and Cumberland. There are seven planning authorities in the Lake District and half a dozen highway authorities, while the Forestry Commission possesses full powers overriding most of these. In order to secure uniformity, the proposal made by the Friends of the Lake District is that a National Park Commission should be appointed by the Government with statutory powers for protective purposes to override other bodies; that the Commission should receive a grant from the taxpayers' money and that it would be responsible to Parliament only. In return for the outlay the public, by arrangement with the land-owners and commoners, would acquire a right to utilize all paths, etc., which have for long been frequented by the courteous permission of such proprietors and commoners. Any other national parks created in the country would be placed under the general control of the National Park Commissioners.

Science News a Century Ago

The Insulating Power of Fluids

IN 1837, Faraday was making researches connected with the induction, and the conduction of electricity by various types of insulators. As is generally known, his observations were entered in his diary in numbered paragraphs, the entries for September 6, 1837, running from No. 3875 to No. 3891. The first few of these were as follows:

"3875. Tried insulating power of some fluids by dipping a glass rod in them and then touching a gold leaf electrometer with the wet part, the finger being also applied to the wet part about the third of an inch from the electrometer. Thus a film of the liquid of about half an inch long formed the communication.

"3876 Oil of turpentine—good and filtered; insulated well.

"3877 Oil of turpentine—old and with water at the bottom of the bottle; discharged the electrometer at once.

"3878 Naphtha (French)—insulated well.

"3879 Oil gas liquid—Do.

"3880 Caoutchoucine—discharged moderately.

"3881 Cocoa nut oil (the expressed solid part)—discharged at once.

"Hence Oil of turpentine, Naphtha and Oil gas liquid appear as if they would do for transinductive media."

Discovery of the *Victoria regia*

AT a meeting of the Botanical Society held on September 7, 1837, the secretary read a communication from Robert H. Schomburgk dated New Amsterdam, Berbice, May 11, 1837, on a new genus allied to the water-lily, which by permission of Her Majesty he had named *Victoria regia*. The discovery of the plant by Schomburgk, in the River Berbice, in British Guiana, was made in January. When on the river he saw something which raised his curiosity, "All calamities were forgotten; I felt as a botanist and felt myself rewarded. A gigantic leaf, from five to six feet in diameter, salver-shaped, with a broad rim of light green above, and a vivid crimson below, resting upon the water: quite in character with the wonderful leaf was the luxuriant flower consisting of many hundred petals. The smooth water was covered with them, I rowed from one to another, and observed always something to admire. . . . We met them afterwards frequently, and the higher we advanced the more gigantic they became".

British Association at Liverpool

ON Saturday, September 9, 1837, the General Committee of the British Association met in the library of the Liverpool Athenæum, the Marquis of Northampton being in the chair. In the course of the meeting it was announced that the Government, at the request of the council, had consented to repeal the duty on the importation of philosophical instruments, and also to extend the Ordnance Survey to Scotland. It was also stated that the council had directed its attention to the establishment of a law of universal copyright, and had entered into communication with M. Guizot, Minister of Public Instruction in France, and Mr. Sergeant Talfourd.

It was submitted and agreed to that admission to the General Committee, then open to the presidents

and vice-presidents and office-bearers of chartered philosophical societies and contributors to the *Transactions*, should be extended to the officers of the Literary and Philosophical Society of Newcastle, the Natural History Society of Newcastle, the Wernerian Society of Edinburgh, the Royal Geological Society of Cornwall, the Geological Society of Dublin and the Statistical Societies of London and Manchester.

Babbage's "Bridgewater Treatise"

IN May 1837, Babbage published "The Ninth Bridgewater Treatise. A Fragment". It was adversely criticised in the *Mechanics' Magazine* of September 9, 1837, in which it was said that "almost every chapter is composed of mere scraps of composition, without any attempt to unite them into one whole; some chapters have no end; many more have no beginning and one at least might be fairly said to have neither beginning, middle nor end. . . . It is perhaps hardly necessary to do more", said the reviewer, "than state the plain fact that the main object of this Ninth Bridgewater Treatise is professedly to raise our conception of the power and wisdom of the Creator, by comparing the mechanism of the Universe with that of Mr. Babbage's calculating engine!"

Indulgent Examiners

THE *Lancet* of September 9, 1837, contains the following story from a correspondent, entitled "A New Method of Passing Apothecaries Hall": "Candidates who are rejected are most strongly recommended to commence crying immediately after the sentence of the Examiners is pronounced; this mode of appeal to the worthies of the Hall being likely to prove effectual for candidates in that predicament. A case in point occurred last week. A great boy on the wrong side of thirty left the room crying aloud. The sentimental event touched the feelings of the examiners and the scientific youth was called back after a few minutes into the presence of the Board, whence he returned to the 'finking' room with his diploma, where he commenced kicking up his heels and laughing most uproariously, and finally placing his dexter thumb to the point of his nose, in an expressive manner, quitted the Hall, perplexed much to know whether the operation of sneering or laughing was most suited to the occasion".

Preservation of Bodies for Dissection

THE issue of the *London Medical Gazette* for September 9, 1837, contains the following description of the method of preserving bodies for dissection invented by M. Gannal, to whom the Academy of Sciences in Paris awarded a prize of 8,000 francs: "The process simply consists in injecting an aqueous solution of an aluminous salt by one of the carotids; some pints are sufficient; after it the body may be preserved exposed to the air for a long time without putrefaction, and sometimes at last dries and is mummified. He uses acetate of alum prepared from the acetate of lead and sulphate of alum and potash; and five or six pints of a strength that will mark 18° on Beaumé's aerometer, are sufficient to preserve a body for five or six months. He has also used simple sulphate of alum for procuring the acetate. With one kilogramme of common sulphate of alum in lumps, 250 grains of acetate of lead and two pints of water, a mixture may be obtained sufficient to preserve a body four months; or common sulphate of alum alone will make one keep for two months".

University Events

CAMBRIDGE.—At King's College, K. P. Harrison and O. L. Zangwill have been awarded Harold Fry studentships, and D. S. Evans has been awarded a Martin Thackeray studentship. At Clare College, Denman Baynes research studentships have been awarded to J. V. Dunworth and T. E. Easterfield for natural sciences and mathematics respectively. At Emmanuel College the external research studentship offered to graduates of other universities intending to commence residence as research students in October next has been awarded to A. G. Ward (Queen's University, Ontario) for research in physics.

DURHAM.—The title of emeritus professor has been conferred on Prof. W. M. Thornton from the date of his retirement at the end of the session 1936-37. Prof. Thornton has been professor of electrical engineering since 1906.

Dr. Emrys Williams has been appointed lecturer in electrical engineering in succession to Dr. J. A. Wilcken, who has resigned, upon his appointment as assistant editor of *Science Abstracts* issued by the Institution of Electrical Engineers.

Societies and Academies

Paris

Academy of Sciences, June 28 (C.R., 204, 1909-1992).

ALFRED LACROIX: A new basaltic type, comparable, from the chemico-mineralogical point of view, with the feldspathic meteorites.

MME. HILDA GEBRINGER: Chance variables arbitrarily connected. Case of convergence according to the law of GAUSS.

FUMIMOTO MAEDA: Nuclei of the Fourier type.

LEON BESCHKINE: The general solution of rectangular plates (plane problems).

JEAN ROUBAUD-VALETTE: A generalization of the operation of Dirac.

GEORGES DARRIBUS: A new form without singularities of the electrodynamic of Born.

ALEXANDRE DUTOUR and FERNAND PRUNIER: The observation of the Sagnac phenomenon by an immobile observer.

JEAN LECOMTE, HENRI VOLKINGER and ARAKEL TOHAKIRIAN: The infra-red and Raman spectra of the chlorobromomethanes.

PIERRE MESNAGE: The molecular emission spectra of some metallic salts.

H. BIZETTE and M. SCHUBERT: Anomalies of the magnetic rotatory dispersion of sulphuric acid solutions of tellurium.

MAURICE COTTE: The calculation of the influence of the space charge in electronic optics.

JACQUES SOLOMON: The origin of the quadrupole moments of the atomic nuclei.

MAURICE DODÉ: The dissociation of native zinc carbonate, a reaction in which a mixed condensed phase intervenes.

RENÉ DELAFLAIE: The vapour pressure of gaseous saturated hydrocarbons at low temperatures in the presence of silica gel. Pressures are given for methane, ethane, propane, normal and isobutane at temperatures ranging from -26°C . to -171°C . Some quantitative separations of these hydrocarbons can be carried out by this method.

JEAN COURNOT and Mlle. LOUISE HALM: Studies on the corrosion of magnesium and some ultra-light alloys protected by deposits on the surface.

MME. LÉONIE WALTER-LÉVY: Magnesium basic chlorocarbonate.

M. LEMARCHANDS and P. PIERRON: The action of bromine on yellow mercuric oxide.

MAXENCE MEYER: The thermal decomposition of the α -diethoxydiacids.

JULIEN DURAND: The major irregularities of the crystalline country of Rouergue and of Albigeois.

RENÉ ABBARD and EDGAR AUBERT DE LA RUE: The existence of the upper Neogene with *Cycloclypous* at the islands of Epi and Malekula (New Hebrides).

EUGÈNE RAGUIN and HENRI VINCENT: An exceptional (hypothermal) type of lead-bearing deposit in the Montagne-Noire.

Mlle. JANE MANUEL: The sexuality of the principal species of the genera *Saccharomyces*, *Hansenula* and *Pichia*.

LOUIS BOUKOURÉ: The constitution of the genital glands in the russet frog after extensive destruction of the germinal line by the action of ultra-violet rays on the egg.

GEORGES CARRIÈRE, PIERRE JEAN GINESTE and EMILE LAINE: The action of the thyroid body on the thymus.

STÉPHAN JELLINEK: Cells with regular geometric deformations without traces of heat action. The action of ultra-short waves (6 metres, 500 watts) on the larvae of *Salamandra maculosa*.

Moscow

Academy of Sciences, C.R., 15, No. 3, 1937.

N. ACHYSEER and M. KRININ: The best approximation of periodic functions derived by summation of trigonometric series.

H. HILMY: The theory of quasi-minimal ensembles.

R. O. KUZMIN: The distribution of values of some arithmetical functions.

B. FESSENKOFF: (1) Eclipses of the moon and the distribution of atmospheric ozone. (2) The infinite universe and the luminosity of the night sky.

N. A. ŠIŠAKOV: An investigation of structures of silica glass, pozzolans and clays by means of electron diffraction (see also NATURE, May 29, p. 927).

S. ŠUBIN and A. SMIRNOV: The scattering of light by the electrostatic field of a point charge from the point of view of the non-linear quantum electrodynamics.

L. I. BELAJEV: Pseudo-extraction and some specific properties of films obtainable thereby.

M. I. DEMENTJEVA, A. V. FROST and E. K. SEREBRIAKOVA: Equilibrium hydrogenation of *n*-butylene to butadiene, $n\text{-C}_4\text{H}_8 \rightleftharpoons \text{C}_4\text{H}_6 + \text{H}_2$.

A. S. SEREBROVSKIJ: Analysis of the allobalance of a chromosome by two markers. Utilization of several quantitative characters simultaneously.

M. F. TERNOVSKIJ: Amphidiploid shoots of the F_1 hybrid *Nicotiana tabacum* L. $\times$ *N. sylvestris* Sp. et Comes.

V. P. OSTRAKOVA-VARŠAYER: *Galleria melonella* L. as a new material in genetical investigations.

O. J. SOBOLEVSKAJA and V. S. BUTKVIČ: Formation of citric acid in the makhorka leaf (*Nicotiana rustica* L.).

Forthcoming Events

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE
(NOTTINGHAM MEETING).

Sunday, September 5

At 8.15 p.m.—Prof. H. Hartridge, F.R.S.: "Illusions of Colour" (Public Lecture at Nottingham).

Monday, September 6

At 10 a.m.—Prof. D. Brunt, Dr. K. C. Lange, Prof. V. Vaisala: "The Upper Atmosphere" (Symposium: Section A).

Dr. Irving Langmuir, Dr. H. Eyring, Prof. H. S. Taylor, F.R.S., Prof. E. K. Rideal, F.R.S., Dr. J. F. Danielli, and Dr. H. J. Phelps: "Surface Action in Biology" (Joint Symposium: Sections A, B and I).

Prof. A. Plant, Prof. B. F. Shields, H. T. Weeks, H. G. Selfridge, jun.: "Retail Distribution" (Discussion: Section F).

Dr. W. B. Turrill, W. J. C. Lawrence, Prof. J. R. Matthews, Dr. T. J. Jenkin and Dr. J. W. Gregor: "Genetics and Taxonomy" (Discussion: Section K).

At 11.30 a.m.—Prof. H. Levi, J. Sargent and J. Wickham Murray: "Technical in Relation to General Education" (Discussion: Section L).

At 2 p.m.—Prof. P. M. Roxby, Dr. L. Dudley Stamp and Prof. C. B. Fawcett: "Culture Regions" (Joint Discussion: Sections E and H).

At 7.30 p.m.—T. M. Herbert: "The Transport of Food" (Public Lecture at Newark-on-Trent).

At 8 p.m.—Sir Gilbert Walker, F.R.S.: "The Mechanics of Sport" (Public Lecture at Derby).

Dr. J. E. R. Constable: "Science in Everyday Life" (Public Lecture at Long Eaton).

At 8.30 p.m.—Prof. J. Gray, F.R.S.: "The Mentality of Fishes" (Evening Discourse).

Tuesday, September 7

At 10 a.m.—Dr. R. E. Stradling, Dr. F. M. Lea, Dr. J. S. Dunn, F. H. Clews, H. H. Macey and Dr. G. R. Rigby, Dr. D. G. R. Bonnell: "Chemistry of Building Materials" (Symposium: Section B).

Prof. Winifred Cullis, Dr. H. Maceo, Prof. R. C. Garry, Dr. L. P. Lookhart: "Physiology as a Subject of General Education" (Section I: Discussion).

Sir John Russell, F.R.S., Dr. Winifred Brenchley, W. Davies, G. E. Blackman, and Mr. Martin Jones: "Pasture Problems" (Joint Discussion: Sections K and M).

At 8 p.m.—Dr. L. Dudley Stamp, Prof. H. L. Hawkins, F.R.S., Dr. J. S. Huxley, Prof. E. J. Salisbury, F.R.S., Sir Daniel Hall, K.C.B., F.R.S., Prof. J. H. Jones: "Planning the Land of Britain" (Joint Discussion: Sections C, D, E, F, K and M).

INSTITUTE OF METALS, September 6-9.—Annual Autumn Meeting to be held at Sheffield.

September 6, at 8.—Dr. D. R. Pye, F.R.S.: "Metalurgy and the Aero Engine" (Autumn Lecture).

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ASSISTANT ENGINEER in the Research Department, Woolwich, S.E.18.—The Chief Superintendent (September 10).

LECTURER IN MINING ENGINEERING in the Denbighshire Technical Institute, Wrexham.—The Secretary and Director of Education, Education Offices, Ruthin (September 11).

CRIMINAL-ROBBER LECTURER IN PSYCHO-PATHOLOGY in the University of Aberdeen.—The Secretary (September 15).

JUNIOR LECTURER IN PHYSICS in the Military College of Science, Woolwich, S.E.18.—The Commandant (September 17).

DEMONSTRATOR IN CHEMICAL PATHOLOGY in the University of Leeds.—The Registrar (September 18).

STATE CHEMIST FOR IRELAND.—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (September 24).

ASSISTANT IN BIOCHEMISTRY in the University of Oxford.—The Whitty Professor of Biochemistry (September 29).

JUNIOR ASSISTANT in the Science Museum Library.—The Director, Science Museum, South Kensington, S.W.7 (October 4).

LECTURER IN PHYSICS AND MATHEMATICS in the College of Technology and Art, Rotherham.—The Director of Education, Education Office, Rotherham.

Research and Industry

IN his presidential address on September 2 to Section G (Engineering) of the British Association meeting at Nottingham, Sir Alexander Gibb took for his subject "Research and Engineering". He pointed out that engineering began as an art; at a later stage it developed into a somewhat scientific but purely empirical practice; and that it is now at the final stage of applied science. The same transformations may be noted in many other industries, though it must be admitted that there is still a great number of industries yet in the second stage of development, and some even in the first. Nevertheless, there is an increasing attention paid in industry generally—and not only in engineering—to the vital necessity of continuous research as being, to quote the words of Sir Alexander, "the only means of continuous progress in an increasingly competitive world".

Sir Alexander Gibb gave a necessarily brief historical survey of the rise and development of research, which is a plant of very recent growth. Apparently he regards the beginnings of the national recognition of the value of research as dating back to less than a century ago, when the Royal Commission was appointed to find uses for a surplus of £213,000, made by the Great Exhibition of 1851. The money was used to purchase land in Kensington Gore, on which were built museums and schools of art, and also to provide science scholarships. Government grants from 1850 onwards to the Royal Society and private donations or bequests went to aid research in mathematics, physics, astronomy, biology, chemistry and general purposes.

In Great Britain, throughout this early period, original research continued to be mainly the work

of individual scientific workers and was carried on chiefly at their own expense. Industry lagged far behind in its recognition of the value of scientific research, and it may be said, indeed, that it is only within very recent times that industry generally has accepted the view that scientific and industrial research is an essential factor in our industrial and national existence. It is also true to add that it needed the lessons of the Great War to open fully the eyes of the Government to the paramount need of systematic scientific research in our industrial organization.

Perhaps nothing in the development of the research movement is more significant than the way in which the distinction between pure and applied science, which was originally as sharp as the distinction between 'Gentlemen' and 'Players' at Lord's, has gradually lost its sharpness and become vague and indefinite. It is not so very long ago that, in many quarters, research into the internal structure of the atom was regarded as a noble and elevating pursuit of pure science, and research on soap as a rather ignoble, if not degrading, investigation—as though an atom were inherently dignified and became disreputable only when it was associated with other atoms to form the molecules of a homely, if necessary, commodity. Indeed, the artificial division between pure and applied science has dissolved perhaps most rapidly in the very laboratories which may seem, at first sight, to have been designed to buttress and perpetuate it. In industrial research laboratories, both at home and abroad, there is abundant testimony to the importance of 'pure science' research—what it is now the fashion to call 'fundamental research'.

The same recognition is a remarkable feature of the experience of those industrial research associations which have been formed under the aegis of the Department of Scientific and Industrial Research. Almost with one voice they are crying out that the time and energies and the expenditure involved—necessarily and rightly involved—in solving *ad hoc* problems of great and immediate importance to the respective industries, leave them with too little time and energy and funds to be devoted to that fundamental research which they recognize as equally vital to the progress of industry. The solution, let it be said at once, demands not the curtailment of one, to make possible the enlargement of the other, but adequate funds to enable both *ad hoc* and fundamental research to be pursued on a sufficient scale.

We may note here that Sir Alexander Gibb says: "There is what one may call true fundamental research—splitting the atom, or extreme low temperature investigation." Perhaps it is convenient to call such research fundamental. It is a little difficult, however, to see how "splitting the atom" is more "fundamental" than splitting the molecule in ordinary industrial cracking processes; or to understand why "extreme low temperature investigation", more than high temperature researches in, say, polymerization or hydrogenation, is "true fundamental research". However, the point is one of small importance. In all cases of so-called industrial research, the ultimate need is nothing less than the full available knowledge of all the factors involved, and these factors include as well those that may conveniently be regarded as 'pure' or 'fundamental' as those of immediate industrial importance. The real aim of industrial research, whether in engineering or in any other industry, should be to elucidate the scientific principles involved, to gain the scientific knowledge needed and to apply the knowledge, in so far as it can be applied, to industrial practice. To achieve these aims it may be necessary to undertake what is called pure or fundamental research, on one hand, and applied research, on the other. But, at bottom, these constitute essentially one research purpose.

Another feature noticed by Sir Alexander in his address is the degree to which, in later years particularly, co-ordination and co-operation in research have become recognized as essential. Sir Alexander quotes the remarks of Mr. Thomas Midgley on the occasion of the award to the latter this year of the Perkin Medal of the Society of

Chemical Industry: "In any earlier age, when science and industry were simply individualistic processes, it is conceivable that some person, by his efforts alone, could have advanced applied chemistry to have justified your Committee to bestow upon him the Perkin Medal. To-day this is no longer so; to advance applied chemistry, even a little, requires the organized efforts of many individuals." This is, of course, true also of industry and manufacture in general. The work undertaken by the various research boards of the Department of Scientific and Industrial Research, and the wide field of scientific and industrial research covered by the activities of the industrial Research Associations, all testify to the vital need to-day of co-ordination and co-operation in research. Scientific research is becoming less and less an individual effort and more and more a matter of team work.

Towards the conclusion of his address, Sir Alexander Gibb directed attention to the fact that, the greater the success of research, the more immediate and drastic is the effect on existing plant and equipment. He says: "Millions are necessarily sunk in fixed assets, which may in a year or two be made obsolete by the development of new methods", and he declares that many valuable inventions have been bought up by vested interests and suppressed, in order to save the greater loss that their exploitation would involve to already operating plant. This particular allegation has been made so often that it is difficult to believe there is not a good deal of truth in it. The lack of data of specific instances of inventions being purchased only to be promptly strangled is, however, a great handicap to any assessment of what the nation has lost and may lose by such a practice. Not many years ago, large commercial combinations were regarded with deep suspicion, as being nothing but price rings. But the findings of a Government inquiry into the extension of trade organizations and combinations did a great deal to allay public mistrust. The question arises whether a similar Government inquiry should be made into this alleged practice of smothering valuable inventions at, or soon after, their birth. It might turn out that the practice neither goes so deep nor is so widespread as popular impression allows. On the other hand, if such an inquiry should reveal a grave public mischief, appropriate measures could be taken. From every point of view, however, it is desirable that precise information should be available on this subject.

Cultural Basis of the History of Science

Famous American Men of Science

By J. G. Crowther. Pp. 414 + 12 plates. (London: Secker and Warburg, Ltd., 1937.) 15s. net.

SINCE the publication of Prof. Hesse's challenging discussion on the social background of Newtonian mechanics at the International Congress of 1931, there have been welcome indications of a new attitude which may do much to rescue the history of science from the disfavour or indifference of the majority of scientific workers. Prof. Wolf's book has made the famous woodcuts of Agricola's treatises on sixteenth century mining technology accessible to a wide circle of readers. The issue of Hooke's diaries and the reprint of the "Heads of Enquiries" have shed a new light on the early days of the Royal Society. Mr. Dickinson's admirable biography of Matthew Boulton has disclosed a mine of information about the scientific renaissance which accompanied the Industrial Revolution. Not least important of recent literature with this new orientation was J. G. Crowther's "British Scientists of the Nineteenth Century".

One of Mr. Crowther's reviewers compared the latter to Mr. Strachey's "Eminent Victorians". The comparison was a just one in so far as the faintly ironical flavour of the author's style placed it among the class of books which may be read painlessly. From another point of view it was less apt. Mr. Crowther is not a writer of footnotes or a biographer in the gentlemanly tradition. He has a vigorous and a unified point of view about the topics he handles. As Mr. James Branch Cabell used the romantic medium to satirize romanticism, Mr. Crowther uses the art of biography to put the individual in his place. That is not to say that he underrates the exceptional capabilities of the personalities he selects or discounts the magnitude of individual differences. What distinguishes Mr. Crowther's treatment from that of Prof. Lenard and a host of imitators who have raised the conventional cult of the scientific worthy to the status of a historical creed, is that he is pre-eminently interested in what circumstances of his situation enable a man of exceptional gifts to be trained in a particular way, how the conditions of his time canalize his curiosity into some specific and profitable channel and how his social circumstances provide him with instruments for solving the problems he tackles.

Great men do not come trailing clouds of glory from the abode where the eternal are. The human zygote—albeit well favoured with genes—does not

attain the stature of international eminence in a social vacuum.

"From the perspective of the history of science," says Mr. Crowther, "the question of personal priority is of no importance. The significant feature of Henry's great paper of July, 1832, is that the phenomenon of electro-magnetic induction was discovered, or about to be discovered, independently at about the same time in Albany, U.S.A., and in London, England. These events show that the progress of science depends far less than is generally believed on the efforts of individual geniuses. . . . As Henry and Faraday made the discovery almost simultaneously, it could not have been of such a unique nature that it could occur only to one investigator of supreme genius."

Mr. Crowther might have made a more topical hit by substituting genes for God when he writes:

"The traditional explanation of why the laws of gravitation were discovered in the seventeenth century is that Newton happened to be born then. As Pope wrote:

'God said: let Newton be, and all was light.'

According to this view, the light of gravitation would have been seen 'in 1665 B.C. instead of A.D. 1665, if God had chosen to let Newton be twenty-three years of age on the former date."

Mr. Crowther's new book, no less noteworthy than its predecessor, follows the same plan and traverses a less familiar terrain. Its four hundred pages are devoted exclusively to four studies: Benjamin Franklin, Joseph Henry, J. Willard Gibbs and Thomas Edison. It deals, therefore, with a longer period of modern science than its predecessor, and the individual portraits are more detailed. Though it appeared first in its American edition, we may anticipate a wider audience in Britain than in the United States. It abounds in incidents of social history less familiar to men of science in Great Britain than to educated Americans. The selection of personalities, though closely involved in the dominant themes of British science, do not include any representatives of the biological sciences, such as genetics, to which the American contribution has been specially noteworthy. It would be interesting to read what Mr. Crowther would have made of the initial impetus which American biology received from the expansion of agricultural technology during the latter half of the nineteenth century. To regret that he

has not done so is a tribute to, rather than a criticism of, the book as a whole. The range of Mr. Crowther's knowledge and the discrimination with which he writes encourages us to ask for more.

The social background of science is so complex that two writers might well handle the same period with great detail and very little overlapping. Some of the main issues which confront the historian of science may be summed up in the triadic formula familiar to readers of crime fiction. The tempo of scientific progress receives new *motive* power from new problems which arise in the technique of navigation, mining, agriculture and other forms of production. New technical amenities, such as the manufacture of cheap and abundant glass of high transparency or the production of cheap amplifiers, provide the *means* for tackling problems which have defeated renewed efforts in the past. New social machinery for the recruitment of a new fund of social personnel—schools and academies, organized professions and scholarships—make *opportunities* for enlisting talent in the solution of new problems. One of the advantages of the biographical treatment which Mr. Crowther follows is that it does not commit him to concentrate on any one aspect of the social background of science to the exclusion of others. At one moment he dwells on the special climatic conditions which favoured Franklin's work on atmospheric electricity. At another he examines the influence of railroad extension on American contributions to electrical communications. Throughout the book he sustains a keen appreciation of the interplay of commercial and professional preoccupations in providing the means of livelihood for scientific workers.

The interest of Franklin for the student of scientific history extends far beyond the fact that he brought the first electrical invention into economic use. The Philadelphia Academy is a halfway house between the Invisible College and organizations such as the Edinburgh Society or the Lunar Society of Birmingham. Franklin, whose interest in electricity was inspired by the work of Hawksbee, Gray and Watson, had close personal contacts with Priestley, Boulton and other notables of the Edinburgh and Birmingham circles. Mr. Crowther insists that his political career and his scientific interests were different facets in the same social pattern. The further advancement of science was then contingent on the rising social influence of the entrepreneur, and drastic political changes were essential to establish it. There is much in the history of the time to show that this view was shared by many scientific men. Both the Lunar Society, among whom Priestley was elected a member of the National

Convention and a delegate for the Department of Orne, and the Manchester Literary and Philosophical Society, when the elder Henry was one of its leading figures, sent official representatives to the Club of the Jacobins.

In the essay on Joseph Henry, first director of the Smithsonian Institution, Mr. Crowther's narrative puts the first beginnings of wireless communication in a new setting, and provides a useful corrective to reiterated emphasis on the cardinal incentive which Maxwell's theory is supposed to have supplied. Starting with Henry's experiments and Varley's lightning protector, the history of radio might well be rewritten from the record of workshop discoveries in connexion with microphone construction with much less reference to the parallel mathematical development of wave-theory.

Like Lytton Strachey, Mr. Crowther has the knack of selecting a situation which is ironical in its own right and needs no comment to embellish it. Such is the story of James Smithson, whose will provided for starting what Taft called "the incubator of American science". Such also are many of the well-authenticated incidents from Edison's history. The following is a sample:

"He made his first invention at Stratford when he was sixteen years old. Night operators were required to send hourly signals to show they were awake. He devised a clock which made the time signals automatically. This enabled him to sleep while on duty and preserve his energy for his own interests during the daytime."

When Edison started putting up telegraph lines between private business offices to exploit his alphabetical dial instrument, he himself says that they slung wires over the house-tops "without asking anyone's permission. Apparently they went to houses and stores which had already had wires supported by the roofs, and told the occupants they were the telegraph men and wanted to see the wires. They were always given permission to go up to them, and while there fastened up their own. This, apparently, is how it was possible for Edison, without any capital, to put up his own small centralised telegraph system in the center of a city. He did not pay rent for the wires slung over the property of others".

The importance of the new school to which Mr. Crowther belongs is that it gives the history of science a new cultural status. The future of scientific progress is not assured by its own momentum. In the past there have been Dark Ages. The recent exodus of scientific men from Germany shows that the prestige of science is more precarious than many would like to believe. In some small measure no doubt the choice between

progress and decay can be influenced by scientific workers as citizens equipped with understanding of agencies which decide the stability of a social culture. Only as an integral part of the story of man's social relationships can the history of science give them this understanding. As such Mr.

Crowther's book has a wide appeal and claims a large audience. Among men of science it should arouse a new sense of social responsibility. Among those who have received a humanistic education it should stimulate a new interest in science.

L. T. H.

Science and the Modern Highway

Principles of Road Engineering

By Prof. H. John Collins and O. A. Hart. (The Roadmakers' Library, Vol. 6.) Pp. xvi + 628 + 21 plates. (London: Edward Arnold and Co., 1936.) 50s. net.

ALL branches of applied science have made rapid progress during the last quarter of a century, and not least that of the science of road building. During this time, we have seen the transformation of our roads from the dusty and pot-holed surfaces of the horse-driven carriage and early motor age to the smooth and clean highways of to-day, and with it the very face of England has also changed in a way that at one time would have been deemed impossible. Physics, chemistry and geology have all been pressed into the service of the highway branch of civil engineering, so that it has been transformed from empiricism to something approaching an exact science.

Great Britain has so far lacked a treatise which deals clearly yet briefly with the principles of highway engineering; the book produced by Prof. Collins and Mr. Hart, linking as it does the more specialized works which form the "Roadmakers' Library" in such an admirable manner, is therefore peculiarly welcome. Its merits are well considered with respect to the series of which it forms a part, since this is intended in course of time to cover the whole field of roadmaking and at the same time to make some reference to present policy in Great Britain regarding the development of our highway system. Thus the taking over of the thousands of miles of trunk roads by the Government—only a proposal when this book was published—is now an accomplished fact, and we may perhaps have yet more far-reaching changes in policy, since the Trunk Roads Act of 1936 was criticized from the Government benches as not going far enough.

For years past, the vexed question as to whether Great Britain should have an entirely new road system, as in the case of Germany and Italy, or whether her roads should be improved by the process of widening, bridge construction and the making of by-passes, has been hotly debated. The latter represents the official view, and it is greatly to the credit of the book under review that it is

so designed as to be capable of use under either policy.

The book opens with a short, interesting history of the development of our present road system, rightly stressing the lack of foresight shown by those responsible. An account of the evolution of the various forms of surfacing follows, and the thorny subject of road accidents is dealt with in a very readable way, the necessary statistics being kept to a minimum. This part of the work leads naturally to a consideration of the factors affecting skidding, corrugation and noise, with an able treatment of economic considerations such as the relation between gradient, type of surfacing and running costs.

The principles of route location are illustrated by reference to the Ballachulish-Dochfour and the new Glencoe roads, the only important works of the kind which have been carried out in Great Britain since the Great War. The value of this part would perhaps have been increased if at least one foreign example of completely new location had been included, though the omission is understandable in view of our present policy of patching an old garment rather than investing in a new suit.

The geological section is clearly set out, the illustrations, here and in the other parts of the work, being most useful and well reproduced. It is unfortunate that the portion dealing with the use of local materials is quite inadequate. Great attention has been devoted to this matter in Canada and the United States, where geology has been applied to engineering problems in a way undreamt of in Great Britain, and a survey on these lines has been carried out in the case of the new Glencoe road, though not by official geologists.

Methods of carrying out preliminary, Parliamentary, location and construction surveys follow, and can be commended, though many readers will probably agree that Chapters ix and x, dealing with surveying proper, could with advantage have been omitted. It is to be supposed that all graduates in civil engineering will have covered the work given in these chapters in their university course, though this criticism may not apply to the matter dealing with aerial surveying. Surveying

for private streets is incompletely described, especially in view of the many legal and other difficulties which beset the paths of the local authorities responsible for the construction of many hundreds of miles of such roads yearly.

Horizontal and vertical curves, so important in view of the ever-increasing speeds of modern traffic, are covered in Chapters xi and xii, as is the subject of super-elevation, the variable super-elevations used in racing tracks being very properly condemned as being unsuitable for highways carrying mixed traffic. It is thought, however, that the two pages given to proving a formula used in work of this kind could well have been omitted and the space devoted to such common matters as the widening and improvement of highways, subjects which are not dealt with. The methods of lay-out of road junctions and crossings show the circular type of roundabout now favourably considered by the Ministry of Transport, though it is thought that one of the Y-junctions shown is capable of improvement. Earthworks, including the application of the valuable mass-haul curve, and drainage works, are well covered, though not all engineers will agree that the Ministry of Health formula for run-off gives satisfactory results, more particularly in the case of small areas of ground.

Road foundations and soil mechanics receive detailed attention, the work under the latter head comprising the results of researches not easily available to practising engineers. It is surprising to find no mention in this section of pitched or hard-core foundations, widely used in road con-

struction generally, while the description of construction of concrete roads would probably have been more useful had diagrams and photographs showing arrangements of forms and other such details, been included. The debatable question of reinforcement in concrete roads is treated from a rational point of view, since this problem still awaits elucidation.

Chapter xviii is disappointing, important surfacings such as water-bound macadam, tarmac and sett paving each being dismissed in a page, footpaths—so much to the fore at present—in a few lines, and the data regarding surface dressing are similarly brief. On the other hand, four pages are devoted to a somewhat arid report of the Metropolitan Paving Committee. It is also questionable whether the nine pages of condensed highway law given in Chapter xix are of much value to the highway engineer, especially since the series of which the work forms a part contains an entire volume on the subject. One also looks in vain in either this treatise or the series as a whole for a really good account of highway administration, dismissed in a few pages in the first volume, which in this respect somewhat belies its title.

It would be invidious to over-stress points of this sort in considering a work dealing, as its title states, with the principles of highway engineering, and the authors are to be congratulated on having encompassed so vast a subject in so comprehensive, readable and authoritative a manner. Their treatise can be justly described as a real achievement and a marked contribution to scientific knowledge.

B. H. KNIGHT.

Indian Hydro-electric Technics

The Hydro-electric Practice in India

By Prof. Bhim Chandra Chatterjee. In 2 vols. Vol. 1. Pp. xi+576+vi. Vol. 2. Pp. v+577-1168+vii. (Benares City: Shiva Narayan Chatterjee, 1936.) 50 rupees.

WRITTEN with an Indian purview by an Indian for Indian students, and produced from an Indian press, it is not altogether easy, nor perhaps quite fair, to judge these two substantial volumes by Western standards. The author is professor of electrical engineering at Benares Hindu University and he has had in mind the B.Sc. course for engineering students at that University, though his object has also been "to guide the engineers entrusted with the task of designing and constructing hydroelectric developments or reporting on their commercial success". He has illustrated the principles of his subject by

reference to current practice in the most important hydro-electric schemes of India. At the same time, he indicates that he has drawn freely from all sources of information; and data and a few particulars are given of installations in Canada, the United States and Great Britain.

This being so, it is a little surprising that in a "Comparative Statement of Dams in the World" (p. 832), the only American example quoted is the New Croton Dam (which, by the by, appertains to a water-supply reservoir) and no reference is made to the outstanding examples of water-power dams at Grand Canyon (Boulder Dam) Grand Coulee, Bonneville and other recent American enterprises, or to the Chambon Dam in France and others elsewhere. Furthermore, the use of the term "unprecedented" from a report (dated 1910) in connexion with the Cauvery River

(Mettur) Dam might dispose the reader, in the absence of comment, to infer that a height of 200 ft. or so combined with a length of 5,300 ft. constitutes something unique, whereas the Grand Coulee Dam, though not quite so long (4,300 ft. crest length), has the much greater height of 550 ft. Recent instances of this kind relating to dams of great magnitude should scarcely be overlooked in an up-to-date treatise.

The author certainly deals with his subject in full and commendable detail. He commences with a good chapter on the conditions, financial and economical as well as physical, under which a hydro-electric development project may be considered feasible. Then he proceeds expertly to the theoretical aspect of the matter, surveying the field of hydrology and hydraulics, explaining the nature and purpose of structural features and plant equipment, winding up with a section of 500 pages (nearly half the contents of the whole work) on hydro-electrical installations in India,

and a few notes on management. Among the installations described are the Tata, Cauvery, Kashmir, Mandi and Andhra.

There is, in fact, an immense amount of information comprised in the sixteen chapters of which the work is composed, a good deal of it quoted from various sources, with the limits of quotation not always clearly defined. The index is moderately good. The print is bold and readable, but a number of typographical errors are in evidence. The photographic illustrations might be clearer and some of the diagrammatic figures are blurred. The block on page 846 is upside down! In comparison with other publications of similar origin, the production is apparently up to Indian printing and book-binding standards, but there is certainly scope for improvement in these respects. Taken as a whole, the work should achieve its purpose as a serviceable manual for the Indian student, and, indeed, be of undoubted value for general reference.

B. C.

Keeping Pace with Physics

The Physical Society

Reports on Progress in Physics, Vol. 3. General Editor: Allan Ferguson. Pp. iv+394. (London: Physical Society, 1937.) 20s. net.

THE annual output of papers in physics, including certain branches of electrical science, is at least six thousand. Few if any libraries contain all the original journals, and the time taken up by research, teaching and administration leaves far too little for the physicist to deal unaided with the bulk and diversity of published papers. Monthly classified abstracts are given in *Science Abstracts* and in *Physikalischen Berichte*. The subscriber to these journals receives each month about 480 fragments of physics in the making, from which he selects the few relevant to his own work and uses them as a guide to the original papers. Some kind of co-ordination of the results of the remainder of papers is needed by all who wish to keep pace with current physics.

The Physical Society's "Reports" are designed to cover most branches of physics at yearly intervals, and some special topics after longer periods. This third volume maintains the high standard of the two previous volumes without quite solving the two difficult problems of uniformity of treatment and freedom from overlapping. For example, sound is covered by an excellent 24-page article giving 78 references. The following article on the measurement of noise occupies 13 pages, gives no references, is written

in the style of an advanced popular science lecture and overlaps the sixth section, technology, of the previous article. Each article is excellent of its kind, but the standard of previous knowledge needed to read the two is quite different. The overlapping is no mere repetition, but is wasted when the volume is used for reference, as there is no index. Contributors, unable to meet and discuss, cannot be held responsible for these two characteristics of the reports, but an editorial committee could perhaps help by issuing more detailed instructions formulated to guide the individuals.

Since the reports can be prepared only by experts, any avoidable overlapping is a waste of part of the world's science man-power. From this broader point of view overlapping with independent publications is also to be avoided. For many years the Chemical Society in its "Annual Reports" has issued excellent reports on crystallography. Why then has another group of workers been set the task of preparing for this volume another independent report in which the same subject is covered, as it happens, less adequately? The Chemical Society "Reports" deal also with radioactivity and sub-atomic phenomena. If it be urged that the reports are prepared from different points of view, it may equally well be urged that if physical aspects of phenomena are relevant to chemistry, then chemical aspects are relevant to physics.

At present, to keep pace with physics it is necessary to consult the "Reports" of the Physical

and Chemical Societies, the *Reviews of Modern Physics*, *Chemical Reviews* and *Die Physik*. With the persistence of the Government restrictions placed upon science, German periodicals will become less and less important. To avoid duplication it is therefore necessary to secure co-operation between only English-speaking societies.

The Physical Society is already broadminded enough to adopt in its *Proceedings* an indexing system designed to help in the international co-

ordination of knowledge. Is it too much to hope that the Society will also try to secure the co-operation necessary to present an annual report holding a unique position in journals published in English? Even the present "Reports" are indispensable in any science library, and readers are heavily indebted to the many individual contributors who have had to sacrifice some of their research effort to carry out the arduous task of digesting hundreds of research papers.

W. H. GEORGE.

Light in the Service of Man

Allgemeine Photochemie:

ein Hand- und Lehrbuch für Studium und Forschung für Mediziner, Biologen, Agrikulturchemiker, Botaniker, usw. Von Prof. Dr. J. Plotnikow. Zweite, umgearbeitete und erweiterte Auflage. Pp. viii + 909. (Berlin und Leipzig: Walter de Gruyter und Co., 1936.) 28.50 gold marks.

PROF. J. PLOTNIKOW, who has considerable experience in theoretical and applied photochemical research, has dealt with different aspects of photochemistry satisfactorily in this treatise under notice. He has divided the subject-matter into four sections, namely: (1) sun and mankind; (2) interaction of matter and radiation energy; (3) statics and dynamics of light reactions; (4) different reactions caused by light.

In the first section, the characteristic properties of different radiations (for example, infra-red, visible, ultra-violet, etc.) and the problem of sight are described in detail. In the same section, the subject of nutrition in the future has been considered in an interesting manner from the point of view of the photochemist. A brief historical account of the development of photochemistry from ancient times appears at the end of this part.

In the second section, the laws of light absorption, reflection and scattering, the phenomena of fluorescence, phosphorescence, bioluminescence, etc., the laws and mechanism of photochemical reactions, temperature coefficient, quantum yield and allied problems, are discussed. It is interesting to note that the summary of quantum yields of different photochemical reactions recorded on pages 230-231 shows that the Einstein law of photochemical equivalence fails in the majority of reactions investigated so far. This fact has also been emphasized by the reviewer.

The mathematical aspect of photochemistry is considered in the third part of the book. The experimental technique of photochemical reactions, which has been considerably developed by Prof. Plotnikow and co-workers, is also discussed in this

section. Cases of photochemical catalysis and equilibrium and the relation between the intensity of the incident radiation and the velocity of photochemical reactions have also been included.

In the fourth part, the author describes briefly numerous photochemical reactions involving inorganic and organic compounds. Most of the literature in photochemistry has been condensed in this section, which also contains a good account of the mechanism of photosynthesis in plants and the function of chlorophyll. Photolysis and photo-oxidations are also adequately considered. At the end, work on the sensitization of photographic plates and films to various parts of the spectrum is summarized: to the infra-red radiation by neocyanine, kryptocyanine, xenocyanine, etc.; to red by dicyanine; to orange red by pinacyanol, nigrosin, chlorophyll, etc.; to orange by pinachrome, cyanine, orthochrome-T, methyl violet, ethyl violet, etc.; to blue green by uranine, acridine yellow, etc.; to ultra-violet by sodium salicylate (alcoholic solution), 'Vaseline' (acetone solution) and other fluorescent substances. A brief account of the phenomenon of desensitization of photographic plates and films with phenosafranine and allied compounds discovered by Lüppo-Cramer has also been included.

As light is utilized in the production of food materials in plants, in nitrogen fixation and in other processes in the soil, in photography, in the production of vitamin, in the treatment of disease and in the preservation of health, in the large-scale sterilization of water and milk, in the detection and testing of different materials, etc., photochemistry is of necessity engaging the attention of numerous workers all over the world, and several important books on this topic have recently been published. The present comprehensive work by Prof. Plotnikow is a valuable contribution to knowledge and should be widely read by chemists, physicists, biologists, agriculturists, medical men and others interested in this subject, which has great possibilities.

N. R. DHAR.

Soil Erosion and its Control

By Prof. Q. C. Ayres. (McGraw-Hill Publications in Agricultural Engineering.) Pp. xi+365. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 21s.

ONE of the effects of the recent world depression has been to focus attention on problems of soil erosion. This has been the case particularly in the United States of America. The preceding years of high prices had led to a rapid expansion of mechanized farming, thereby reducing the man-power required to farm arable land. So long as prices ruled high, little notice was taken of the diminishing returns obtained from such expansive and continuous cropping, but as soon as the bottom fell out of the market, farmers discovered, almost overnight, that they could no longer carry on.

It was soon made clear that this was largely due to soil erosion and that the damage thus caused was increasing at an alarming rate. Whereas in 1910 it was estimated that ten million acres of farm land were ruined and abandoned, this figure had increased by 1935 to between thirty-five and fifty million acres. For years previously that "tireless little band of erosion technicians" to whom this book is dedicated, had been as a voice crying in the wilderness, and it required the effects of the depression forcibly to bring the position to the notice of the administration, which lost no time in forming this band of workers into the nucleus of a Soil Conservation Service. This Service, besides continuing research, was able to find employment for large numbers of farm workers and other unemployed in an endeavour to control soil erosion.

Since the initiation of this Service, much has been published in the form of bulletins, leaflets, etc., on soil erosion and its control. The author of the present work has collected and arranged this information under suitable headings, and the diagrams, tables, charts and numerous illustrations add much to the value of the text. Though based entirely on American experience and American farming conditions, the book should prove of value to those in other lands where somewhat similar problems and circumstances prevail.

Revisiting my Pygmy Hosts

By Paul Schebesta. Translated from the German by Gerald Griffin. Pp. 288+31 plates. (London: Hutchinson and Co. (Publishers), Ltd., 1936.) 18s. net.

AFTER two visits to the pygmies of the Congo in 1929 and 1930, Dr. Schebesta found himself constrained to pay them a third visit to obtain supplementary data. On this occasion his objective was in the area of Lake Albert and his hosts the Bambuti, as they call themselves. He has thus completed the tour of both the eastern and the western pygmies.

In this story of his sojourn among the little people of the forest, the author has purposefully omitted any formal account of organization and culture where it does not differ from that described in his earlier work. Here again negroes and pygmies live in a relation in which each supplies something lacking in the economy of the other. The negroes need meat

and the pygmy hunter supplies it: in turn, the pygmy needs bananas and vegetable produce, which is obtained from the negro gardens lacking in the pygmy culture.

Dr. Schebesta's lively picture of his relations with his pygmy people affords his readers an opportunity of appreciating their mentality. He has also taken full advantage of his informal method of description to demonstrate the actual working of their social and cultural organization and their magico-religious beliefs. The author is more than ever convinced that the culture of the pygmy is of purely forest origin, and that they are its aboriginal inhabitants.

Exercices d'analyse

Par Prof. Gaston Julia. Rédigés par Dr. Georges Bourion. Tome 4: Équations aux dérivées partielles du premier ordre. Pp. v+230. (Paris: Gauthier-Villars, 1935.) 60 francs.

THIS is the author's fourth volume of exercises in analysis. It is devoted mainly to partial differential equations of the first order, and consists of a discussion of some 55 problems taken from examination papers set at the Sorbonne for the Certificate in Calculus and from Part II of Édouard Goursat's "Course in Mathematical Analysis". The questions selected range from total differential equations to be solved by Bertrand's method, to simultaneous systems and problems in geometry involving partial equations. The solutions are not only complete, but also are characterized by their clarity and elegance. In nine cases, alternative methods, geometrical and analytical, are considered, whilst problem 53 is provided with three solutions. Relevant extensions, particular cases and applications are also indicated wherever possible.

To teachers and students of differential equations, this book should be extremely valuable.

F. G. W. B.

A Marriage Manual:

a Practical Guide-Book to Sex and Marriage. By Dr. Hannah M. Stone and Dr. Abraham Stone. English edition edited, and with an Introduction by, Michael Fielding. Pp. 352. (London: Victor Gollancz, Ltd., in conjunction with John Lane, The Bodley Head, Ltd., 1936.) 7s. 6d.

THE admirable little work by Dr. Hannah M. Stone, medical director of the Birth Control Clinical Research Bureau of New York and Marriage Consultation Centre, and Dr. Abraham Stone, surgeon to the Sydenham Hospital and director of the Marriage Consultation Centre, is written in the form of imaginary conversations between a physician and a young couple about to be married. The subjects on which the pair seek enlightenment are fitness for marriage from the psychological, sexual and eugenic points of view, the anatomy and physiology of the sexual organs, fertility and sterility, prevention of conception, venereal diseases, the art of marriage including the technique of coitus, psychical and somatic incompatibilities and health in marriage. A bibliography of recent English and American literature is appended.

Noise and the Nation*

By Dr. G. W. C. Kaye, O.B.E.

SIMULTANEOUSLY with the remarkable growth of applied acoustics, there has gradually developed in Great Britain a public consciousness of the insidious growth of the social evil of needless noise—a pernicious by-product attributable in great part to an increasingly mechanized civilization. With this growing realization, the nation is beginning to demand and to receive protection against the nuisance of outrageous noise whether generated by private or public bodies. It is looking for ways and means of mitigating excessive transport noises, particularly on the road and in the air, and it is seeking to know why in modern houses or flats it should not be accorded adequate privacy against the natural, though sometimes unreasonable, noises of neighbours.

THE MEASUREMENT OF NOISE

It is common knowledge that most noises are complex in character, containing a variety of components which may be distributed over the entire auditory ranges of frequency and intensity. Such a physical constitution lends itself to objective measurement and analysis, but apart from the psychological aspects, there are subjective factors of prime importance to the listener, namely, pitch, timbre and loudness, and these sensations are not readily appraisable. Experience indicates, however, that while the composition of a noise is not to be ignored, sheer loudness is the determining factor in most cases of annoyance caused by noise, so that the problem largely resolves itself into the correlation of the sensation of noisiness (as assessed by the ear) with the associated energy, which can be quantitatively measured by physical instruments.

Let us first consider the measurement of acoustical energy. For the purpose, we need an intensity meter, this commonly consisting of a microphone and amplifier together with a suitable rectifier and indicator. Moving-coil or ribbon microphones are sometimes employed, though for fundamental work the condenser or the crystal microphone is preferred despite the lower sensitivity. Whatever the microphone used, it is usually calibrated by direct interchange comparison under appropriate

conditions with a standard (pressure) microphone of the condenser type, which in turn has been fundamentally calibrated in absolute units by means of either the Rayleigh disk or the piston-phone.

The Rayleigh disk depends for its operation on the tendency of a small thin glass disk suspended from its edge by a fine fibre to set itself at right angles to a sound field. The torsional constants of the system and the degree of deflection of the disk afford the sound particle velocity, the corresponding sound pressure being calculable from the known relations in the field. The measurements are made either in a stationary-wave pipe or in a room with highly absorbent walls.

The piston-phone, which measures sound pressures directly, consists essentially of a small cavity, one face of which is closed by the diaphragm of the standard microphone, the opposite face consisting of a small piston connected to the moving coil of a loudspeaker unit. The amplitude of motion of the piston, when it is set in vibration, is measured optically and enables the corresponding sound pressures in the cavity to be calculated.

So much for intensity measurements. As regards the associated loudness levels, we turn to auditory diagrams of the ear, such as those of Fletcher and Munson. The various loudness contours for pure tones of different frequencies show that while loudness and energy are manifestly related, the two do not normally keep in step, particularly for notes of very high and very low frequencies. At feeble intensities, the ear exercises pronounced selective preference for notes of medium frequency, and it is only at high intensities that equal increments of energy produce even approximately equal increments of loudness. Furthermore, the thresholds of hearing are much higher for high and low frequencies, so that the corresponding ranges of intensity with which the ear can deal are more restricted than for notes of medium frequency. The situation is worsened in the case of complex sounds or noises since the loudness is affected by their character, there being in general no simple relation between the loudness of a noise and the energy-loudness characteristics of its several components. It is evident that an energy meter, such as a microphone system, cannot unreservedly be used as a direct measurer of loudness.

* From the presidential address to Section A (Mathematical and Physical Sciences) of the British Association, delivered at Nottingham on September 2.

THE DECIBEL AND THE PHON

The next step in the measurement of noise is to equip ourselves with units and standards of loudness. In this connexion, we have to cater for the enormous intensity range of the ear, particularly for notes of medium frequency, where the greatest intensity that can be tolerated (the threshold of pain) is some 10 million million (10^{12}) times that corresponding to the threshold of hearing. In such circumstances, we turn, as always, to a geometrical rather than an arithmetical scale, and the unit adopted for the purpose is the *bel*, which is a ratio signifying a 10-fold increase in intensity, power or energy. Two bels signify a 100-fold increase, three bels a 1000-fold increase, and so on.

Equipped with such seven-league boots, and starting at a zero approximating to the threshold of hearing, we can traverse the entire auditory intensity range for a medium-frequency note in as few as thirteen geometrically progressive steps. But the steps are too big for practical convenience and so it is usual to speak of a range of 130 *decibels*, which provides a serviceable energy scale. Arithmetically, a decibel (db.) denotes approximately a $5/4$ energy increase (that is, antilog $1/10$), two decibels a $(5/4)^2$ increase, three decibels a $(5/4)^3$ = a 2-fold increase, . . . 10 decibels a $(5/4)^{10}$ = a 10-fold increase, that is, a bel. More generally, two similar sounds of intensities I and I_0 and corresponding acoustical pressures p and p_0 are said to differ in intensity by n decibels when

$$n = 10 \log_{10} (I/I_0) \\ \text{or } n = 20 \log_{10} (p/p_0)$$

If I_0 or p_0 corresponds to some selected zero, then n becomes the number of decibels above that zero level.

Thus provided with an acoustical intensity scale, we can proceed to set up a loudness scale which is based on the accepted ability of the average individual to compare and match loudness. To this end (just as in photometry we make use of a standard candle) we need a standard sound; and for the purpose a pure reference tone is chosen, which, on the British Standard Scale, has a frequency of 1000 cycles per second. We also require a zero of loudness at or near the threshold of hearing, and this is arbitrarily adopted as corresponding to a pressure of 0.0002 dyne per sq. cm. If now we operate the reference tone by successively increasing decibel steps of energy, the associated changes of loudness are expressed in numerically identical steps on a scale of *phons*. That is, if the reference tone is excited by an intensity of n decibels above the zero, the loudness is n phons. The equivalent loudness of any other sound or noise is evaluated by matching it by ear

under specified conditions against the suitably adjusted reference tone, the numerical value of the latter in phons then giving the equivalent loudness of the sound to be measured. Thus by this procedure we have set up a subjective scale of equivalent loudness, the unit being the phon.

It happens that a phon corresponds roughly to the smallest difference of loudness which can be detected by alternate listening, in the case of a sound of medium frequency and moderate loudness. Experience shows, too, that for many loud noises of common occurrence the loudness level in phons is approximately equal to the intensity level in decibels—a convenient relation for many purposes.

A number of different zeros of loudness have unfortunately been employed in the past; for example, 1 millidyne per sq. cm., which results in numerical values of loudness some 14 phons less than with the British Standard zero. In Germany the phon is based on a zero of 0.0003 dyne per sq. cm., which is equivalent to a 4 db. difference from the B.S. zero. As, however, a different method of listening is employed, the slight discrepancy between the two scales is not known exactly. The American scale agrees with the British, except that in the United States it is customary to use the decibel not only for expressing intensity measurements, but also for loudness levels, it being implied in the latter case that the decibel figure quoted refers to the energy level (above the arbitrary zero) of the standard tone when it matches the sound to be measured. As already mentioned, the British Standards Institution recommends that for greater clarity the decibel should be restricted to energy ratios; and in its definition of the phon, the Institution kept open the way for eventual international agreement on the unit of equivalent loudness.

Happily such agreement came about at an international conference held in Paris last July, when it was unanimously agreed that the decibel and the phon should be adopted respectively as international units of intensity level and equivalent loudness, full agreement being secured on questions of the reference tone (1000 cycles per second), the reference zero (0.0002 dyne per sq. cm.) and the technique of listening. All these matters are in accord with the definitions in the acoustical glossary of the British Standards Institution.

NOISE METERS

Subjective noise meters.—Subjective noise meters depend on the equality matching of the loudness of a noise, as heard by the ear, with a reference tone (usually a pure tone of specified frequency and of graduated intensity) as heard in a telephone

earpiece held tightly against one ear. The reference tone may be produced by an electric buzzer, valve oscillator or other means, various frequencies (for example, 1000 or 800 cycles per sec.) or mixed tones being used in commercial instruments. The usual Barkhausen technique involves simultaneous listening to the noise and the reference tone, but experience indicates that inconsistencies which are found to arise in aural measurements under such conditions are largely resolved when the two sounds are heard alternately for periods of not less than a second. Such a technique has been

unexpected or single impulsive sounds, the aural assessment presents great difficulties to the average observer.

Objective noise meters.—The problem of the designing of objective sound and noise meters, which has received much attention both in Great Britain and abroad, is of considerable complexity. The ideal aimed at by objective meters is to be able to measure every type of sound and noise on the subjective scale of phons, that is, to simulate the selectiveness and response of the average ear in all circumstances.

Approximate loudness levels of common noises.

BS Loudness scale of phons

Fig. 1.

facilitated by Churcher in a subjective meter employing two earpieces, so that either the noise or the reference tone can be heard in turn using both ears simultaneously.

Subjective meters are useful for certain purposes, but the aural judging of equality of loudness of the reference tone and of a noise very different in character is not always easy. Observers are found to differ widely in their judgments, and the same individual is not always consistent. The accuracy of appraisal of a single observer is normally low (say 5 phons), and a team of trained observers is essential for higher precision (say 2 phons). In the case of

sounds, the inertia of the instrument has to be of the right order to give readings corresponding to average aural appraisal.

There can be little doubt that the future of sound or noise measurement, from a practical point of view, lies with the objective meter. Even in its present state of development, its practical convenience often outweighs its limitations. It is free from personal bias, rapid in action and direct reading, and can be put into the hands of an untrained observer. Furthermore, as a dial instrument, it is well adapted to the enforcement of regulations or specifications.

The various objective meters on the market all consist essentially of a pressure microphone connected to an amplifier provided with calibrated control, followed by some type of rectifier and an output indicator. As a first essential, objective meters are constructed to give the same reading for a range of steady pure tones which sound equally loud to the ear whatever the frequency. This is achieved by introducing into the amplifier electrical networks designed to modify the shape of the frequency characteristic so that it imitates the ear sensitivity at selected loudness levels. If the network is omitted, the meter measures intensity levels. Objective meters should be further designed to simulate the salient characteristics of the ear in dealing with either steady or impulsive sounds. For example, the ear does not record full strength until a steady sound has persisted for about one-fifth of a second, and in the case of pulsating

NOISE-LEVEL MEASUREMENTS

In connexion with problems of noise abatement, the National Physical Laboratory has made measurements and analyses of many noises of very varied origin. The positions which some of these noises occupy in a scale of phons are shown in Fig. 1, the upper half of which includes various noises the abatement of which would be acceptable in many circumstances. This is illustrated by the homely test which most of us apply as a test of background of noise, namely, the ease with which conversation is possible. At 60 phons, conversation is 'comfortable'; at 90 phons, difficult; and at 110 phons, virtually impossible.

Among the noise problems on which the Laboratory has been consulted in recent years, are the mitigation of the noises associated with aeroplane cabins and engine-testing factories, trains, ships, tube railways, buses, motor horns, pneumatic drills, printing works, transformer substations, cathedrals, assembly halls, business offices, flats, miniature rifle ranges, building operations, and so on. Assistance is also being given in connection with the Home Office experiments on air-raid warnings.

The loudness of a noise depends, of course, on its remoteness and to a less degree on its environment. The inverse square law appears to be followed fairly exactly in the open for average sounds such as those of motor vehicles. In a room or a tunnel, the law does not hold and a noise sounds louder than it would outside, owing to the building up of the sound level by multiple reflection. Similar conditions prevail in a narrow busy

street and contribute to the noise discomfort of the occupants in the upper stories, though to a pedestrian the noise of, say, a passing car is but little louder than in an open space. Incidentally, drivers of cars are familiar with the sudden access of high-pitched components from the engines, exhausts or tyres of their cars as they pass reflecting walls or fencing or even minor way-side objects such as tree trunks or telegraph poles.

One has also to remember that the path of a sound may appreciably modify its composition. For example, the high-frequency components may be abnormally reflected or absorbed as compared with lower notes which tend to pass through or round obstacles. Even in the open, a hedgerow or a barrage of trees may, to a limited extent, so serve as a muffler of traffic noise. The high-pitched components of a sound may further be selectively enfeebled in passing over different types of ground, for which the sound absorption may be three or four times as much for high notes as for low. To judge by experience, the absorption figures for newly fallen snow must be rather high, though I am not aware that they have been measured. High-frequency components may also be selectively absorbed by the air itself if it is humid. Knudsen has shown that the effect is due to interaction between the oxygen and water molecules, the nitrogen playing no part. Incidentally, he estimates that if we lived in an atmosphere of oxygen at a humidity of about 20 per cent, the high notes of the violin and piccolo would be completely inaudible 50 yards away.

(To be continued.)

The Sex Ratio*

By Prof F. A. E. Crew

THE subject of the numerical proportions of the sexes in a population necessarily appeals to so many interests that it is not surprising to find that considerable attention has been paid to it. But so complicated are the problems that cluster around it that even yet our understanding of the significance of the sex ratio is still very incomplete. Recent developments in cyto-genetics have removed many of the difficulties that have surrounded this subject, so that it is possible now to re-examine the problem more hopefully.

The Registrar-General's Report for 1935 shows that the secondary sex ratio was 105:100; that

the sex ratio among those babies who died during the 7th-9th months of intra-uterine life was 110:100; that there is a remarkable swing in the sex ratio, a numerical preponderance of males amongst the earlier age groups of the population giving place to a numerical equality of the sexes amongst the 15-19 year olds, whilst amongst the 20-24 year olds the females actually begin to outnumber the males; and thereafter, as age group succeeds age group, this female numerical ascendancy progressively increases until, among the 85's and over, there are more than twice as many women as men.

This swing in the sex ratio from high to very low is shown to be the result of a sexually selective

* From the presidential address for Section D (Zoology) of the British Association, delivered at Nottingham on September 2.

mortality, for the mortality tables make it clear that at all ages relatively more males are removed from the population by death.

A consideration of these and similar facts ultimately leads to the conclusion that in the case of man, for some reason or other, the male, in virtue of his maleness, is less viable than the female, and that, in unfavourable circumstances, both pre-natally and post-natally, the male, because of this greater inherent fragility, suffers more easily and more severely than does the female, and is removed from the population by death in greater numbers. Furthermore, since this selective elimination of the male occurs before, as well as after, birth, it follows that the primary sex ratio is probably considerably higher than the secondary sex ratio.

A comparison of the secondary sex ratio in different countries, in town and country, as affected by migration, amongst legitimates and illegitimates, amongst whites and coloured, living under the same conditions, in different social strata, and in its relation to infantile mortality would seem to show that the whole course of sex mortality in pre-natal life, in infancy, and in all subsequent age periods is consistent with the view that the male in man is the inherently weaker sex, more prone on account of his relative constitutional weakness to developmental anomalies, to congenital debility and to death from diseases of all kinds.

Male must be contrasted with female in an attempt to discover the cause of this, and a study of the sex ratio in other mammals, birds and insects, wild and domesticated, both in the open and under the controlled conditions of experimentation, must be made, for, in this matter of the sex ratio, to know only man is to understand nothing.

Male differs from female in genetic constitution. In the case of man the male is the heterogametic sex. This being so, it follows that in the homogametic female a mutant recessive gene in one X can be cancelled out by its wild-type dominant allele in the other, whereas the same recessive gene in the single X of the heterogametic individual is unchecked and unrestrained and is expressed to produce its full effect. Upon this firm basis of ascertained fact, the sex-linked lethal theory, which seeks to account for the sexually selective mortality and the swing in the sex ratio, has been built.

It is clear that genetic lethals exist in considerable numbers in all animal and plant stocks that have been subjected to genetical experimentation. They are genes which can be mapped and which have an effect upon the secondary sex ratio that can be predicted. But since differences in chromosome

constitution may imply more than a difference in respect of sex-linked lethals, they may also mean a difference in genic balance. It may be that this difference is itself the cause of unequal mortality, though it is difficult to regard the male as being less well-balanced genically since he has endured as long a course of selection as has the female, and it would be expected that dosage compensation would ensure a proper balance in each sex regardless of dosage ratios.

There are other genetic differences between the sexes which are sex-limited and not sex-linked. It is established that many defects and derangements in man, formerly regarded as recessives, are partial irregular dominants, and that many of these are more often and more completely expressed in the male than in the female. Many characters previously regarded as sex-linked are now known to be sex-limited, being expressed only in the male.

There are other differences, metabolic and physiological, which quickly appear in development and which give rise to endocrinological differences which, when once established, take charge of the further differentiation and the maintenance of sexuality in the higher forms. The initial genetic constitution would seem to determine which of two alternative types of differentiation shall occur and, with the incoming of the gonad and the rest of the endocrine system, maleness or else femaleness becomes finally and firmly established. These two states are to be distinguished by sustained differences in oxidation rate. Experiment has shown that the higher metabolic rate of the male renders him less resistant to unfavourable conditions and more prone to death.

A survey of what is known of the sex ratio amongst livestock and laboratory animals shows that, in general, the male amongst them shares with the male of man a relative frailty and endures a selective elimination both before and after birth.

The figures for birds are somewhat confusing. As a whole, they seem to show that it is the heterogametic sex (the female in birds) upon which death falls more heavily pre-natally. If this is so, it can at once be decided that in the heterogametic mechanism itself a factor of importance is to be found.

As a general rule, the males of all groups, except those derived from wide crosses in which genic balance is more likely to be unusual, appear to show a relatively low viability, irrespective of their homo- or heterogamety, and the difference in the death rates of the sexes appears to be as much correlated with sexuality itself as with any particular type of chromosome or gene equipment. That this should be so is perhaps not surprising

when the relative reproductive values of the sexes are compared. The major task of one generation of gamete producers is the production, economically and efficiently, of a succeeding generation that numerically will be in harmony with the conditions and resources of the habitat. That of the females of a generation is the production of the requisite number of ova; that of the males the production of spermatozoa in numbers sufficient to make the fertilization of every available egg highly probable. The number of spermatozoa required will be determined by many factors—for example, the variety of the fertilization process, the pre-natal and post-natal relations of mother and offspring, the relationship of male to female in respect of parentage. If the male is merely a fertilizing agent, then economy and efficiency are observed if the male dies *in coitu* or is for other reasons shorter-lived than the female, so long as there are more or less equal numbers of males and females of the age when fertilization occurs. If the male is concerned with the protection of and food-finding for the female and her young, then the length of life of the male might be expected to be related to the duration of the period of dependency of the young upon the parents and of the female upon the male, and it might reasonably be assumed that when the male has served his purpose he would be removed so that savings in food energy could be effected and used for further reproduction.

Reference has already been made to the fact that in the Registrar-General's Report for 1935 the sex ratio most nearly approached equality amongst those in the population aged 15–19 years. In the Report on the Census of Scotland, 1931, table 31, vol. 2, it is seen that in this human population, though between the ages of 0–14 there were more males than females and between the ages of 20–100 there were more females than males, the sex ratio of those in the population between the ages of 15 and 19 years was equality. It can be stated, therefore, that in the case of these human populations, the sex ratio is equality only amongst those who stand at the threshold of their reproductive prime. This fact is surely not without significance. The age group in which the sex ratio is equality consists of those who, biologically if not socially, are newly equipped for ardent reproduction. Amongst them there is no surplus: there are equal numbers of males and females. If, during the biological evolution of man, pair-mating attached to itself a definite and positive value, it would be expected that all the mechanisms concerned in the establishment of a sex ratio of near equality among the 14–19 age group would, through selection, come ultimately to be related harmoniously to this end.

Implied in this suggestion is yet another: that in the case of any population of living things and under the conditions that exist in any given place and at any given time, there is an optimum sex ratio amongst those of the ages associated with the fullest expression of the reproductive function, and that through selection all the mechanisms, whatever they may be, which influence this are fashioned into harmony with this 'reproductive' sex ratio. It is necessary, therefore, to discuss the meaning in biological philosophy of mutation, sex and heterogamety, all of which are intimately concerned.

Mutation is a mechanism that has become adapted and elaborated for the provision of material possibilities of evolutionary movement. It takes the form of the replacement of one gene by an allelomorph—the substitution of a gene that, having been tested and found worthy, has come to be in harmony with the rest of the genotype, and through this with the conditions of the external environment, by another, the merits of which have yet to be determined. More often than not, therefore, mutation implies a disturbance of an equilibrium within the genotype itself, and between this and the external environment. It is usual, therefore, to find that mutation leaves the genotype less in harmony with the existing external conditions than was that which it has replaced. Mutation, the inception of a new heritable variation, thus usually equips its possessors with a handicap, imposing on them a disadvantage that can range from inconvenience to complete lethality.

Sex is the mechanism that has become adapted for the dispersal of a mutant gene amongst a population. Through its exercise a new gene can become incorporated into a variety of genotypes, and thus given the opportunity of finding itself associated with other genes with which it can interact. It is established that the quality of the action of a gene is largely determined by this interaction with others, for, as judged by its effects upon the life processes of the zygote, it can exhibit disadvantageous properties when in one gene association, advantageous when in another. For the quiet dispersal of a mutant gene in this way it is necessary that it should be recessive, initially at least, to the gene that it has displaced, for then it can pursue a cryptomeric existence for a considerable period of time.

If the great usefulness of sexuality lies in the opportunities it provides for variety in gene recombination and for the exercise of selection, then its advantages will be best exploited when, among those about to reproduce, there is a sex ratio of equality. This observation would not seem to apply to those instances in which gene combinations that are common or are exceedingly rare are

concerned, but a sex ratio of equality among the parents would seem to provide the greatest variety of recombinations in the offspring in the case of gene combination of intermediate rarity. Be this as it may, a device for the production of a sex ratio of equality has certainly been elaborated.

Heterogamety is a mechanism that has become adapted for the production of a primary sex ratio of equality. In its evolution in the higher forms it has taken the form of the replacement in one sex of an X-chromosome by a wholly or largely non-homologous Y-chromosome. The heterogametic sex, therefore, now possesses one X-chromosome, the homogametic, two. An indirect result of this evolution has been that a recessive mutant gene in the differential segment of the X-chromosome is at once uncovered in the case of the heterogametic individual, and so, if in its action such a gene is disadvantageous, deleterious or lethal, to it no time is allowed for the finding of modifying company and for the pursuit of its own evolutionary development. It is expressed and tested within a very short time of its first appearance, and should it cripple or kill, it is the heterogametic sex that is affected. In this way the sex ratio becomes modified, for the heterogametics either die before birth or else their early post-natal mortality is greater than is that of the homogametics. It is somewhat surprising that so few sex-linked lethals have so far been discovered in mammals. It would seem that the differential segment of the X is relatively insignificant and that the cross-over portion, which could not yield a differential mortality since its genes would not automatically be expressed in the male, is relatively large.

It is thus possible to look upon the inequality in capacity for continued life between the sexes as being partly of the nature of an evolutionary oversight due to a lag in the development of a harmonious relationship between the mechanisms of mutation and heterogamety. But this disharmony has been repaired by the invention of a supplementary device which can provide a compensatory primary sex ratio, high in those species with male heterogamety, low in those in which the heterogametic sex is the female. It is established that in many, though not in all, mammalian stocks, the primary sex ratio is much higher than is the secondary, and it is in such stocks that there is much sexually selective mortality operating to the disadvantage of the heterogametic sex. This being so, it seems reasonable to entertain the view that these three variables—the primary sex ratio, a sexually selective pre-natal and early post-natal mortality and the optimum reproductive sex ratio—are somehow related, the dimensions of the first being connected with the amount of the second.

Should this prove to be the case, then it would follow that in general the greater the incidence of mutation, the more common the sex-linked recessive lethals and the greater the difference in the sex incidence of mortality in adolescence in a stock with male heterogamety, the higher will be the primary sex ratio; and, conversely, the rarer mutation is, the fewer the lethals and the less the difference in the sex incidence of mortality between conception and reproductive prime, the nearer to equality will this primary sex ratio be.

This suggestion, of course, demands that there should be genes which affect the functioning of the heterogametic mechanism, and also that it should be possible, by continued selection, to modify the primary sex ratio of a stock. This will be equality when the heterogametic sex elaborates its two kinds of gametes, X- and Y-chromosome-bearing respectively, in equal numbers, and when both of these are equally functional in fertilization. Conversely, the primary sex ratio will be removed more or less from equality if and when the two forms of gametes are not produced by the heterogametic sex in equal numbers, or when, between these two forms, there is functional inequality. The fact that in those instances where the primary sex ratio is not equality it is the Y-bearing gamete that is either produced in greater numbers or is greatly advantaged in fertilization, so that more XY than XX gametes are produced, is of great interest in view of the observed fact that it is the XY zygote that suffers more through the action of sex-linked lethals.

It has been shown to be possible, by continued selection within an animal stock, to produce high and low sex ratio strains, and thus it would appear that there are genes which can be concentrated in a genotype which, in their action, influence the heterogametic mechanism affecting either the relative production of the two kinds of gametes produced by the heterogametic sex or else their relative functional ability. If, as seems to be the case, the male in many forms and irrespective of his chromosome constitution is the weaker sex, then in those instances in which the male is homogametic an excess of X-chromosome-bearing ova is demanded from the heterogametic females or else there must be some form of selective fertilization, the X-ova being more often or more readily fertilized.

That genes which lead to the production of X- and Y-bearing gametes in unequal numbers do exist is shown very clearly indeed by the work of Sturtevant and others. One such gene was discovered as long ago as 1922 (Morgan, Bridges and Sturtevant, 1925) in a strain of *Drosophila affinis* in which occasional males were found to produce families consisting almost entirely of females. A

definite X-borne gene was suspected. Gershenson (1928) found a similar gene in *Drosophila obscura*, and showed that it was indeed resident in the X-chromosome. A male carrying this gene produces very few sons, regardless of the genetic nature of his mate. More recently, (1936) Sturtevant and Dobzhansky have found that this gene has a very wide geographical distribution in both races of *Drosophila pseudo-obscura*, that it is sex-linked, lying in the right arm of the X-chromosome, and being associated with a small inversion. Cytological study has shown that in these cases the X-chromosome undergoes equatorial division at each meiotic division, whilst the Y-chromosome degenerates, with the result that a male carrying this gene produces nearly all X-sperm instead of the usual 50 per cent. It is to be expected, of course, that a sex ratio gene of this kind would be discovered only if its effects upon the sex ratio were profound. But the existence of such genes permits us to assume that other genes of the same kind, having less severe effects upon the heterogametic mechanism, also exist and are responsible for minor distortions of the sex ratio. If such

genes do exist, then, of course, they can be incorporated into, or extruded from a genotype, and upon them selective agencies can work their will. These sex ratio genes may perhaps provide a partial explanation of the observation that hybridization commonly is attended by marked distortions of the secondary sex ratio.

But all this is so much speculation, and the only justification for toying with such ideas is that criticism may be aroused and experimentation launched. I have presented evidence to show that three possible causes of sex differences in mortality have to be considered: (1) sex-linked lethals, (2) sex-limitation of defects and derangements, and (3) sex-dimorphic physiological and endocrinological differences. It seems probable that sex-linked lethals play only a minor part and that the defects and derangements that have come to be manifested only or more completely in the male owing to his relative unimportance in respect of propagation, constitute the major cause, though as yet too little is known of sex differences in respect of hormones and their effects to permit us to regard these as unimportant.

The British Association at Nottingham

THE British Association opened at Nottingham on Wednesday, September 1, at a time when local residents feared that a pleasant spell of very fine weather was to be rudely broken; but after a severe storm had passed over, the Association settled down to enjoy days of bright sunshine. The attendance of more than two thousand members is regarded as quite satisfactory, and there is no doubt that those visiting the city for the first time were definitely impressed by the delightful setting of the University College and the accommodation it provided. The opening presidential address on the history of evolutionary thought was well supported, and Prof. W. W. Watts, in moving a vote of thanks, suggested that the fact that Sir Edward Poulton had a son who was president of a Section provided a proof of natural selection.

The presidential addresses to the Sections were crowded. Mr. H. G. Wells had some striking things to say about education, but, so far as one could judge, they served only to increase the admiration and adulation of the professional members in his audience. His contentions were, in a way, supported by Prof. E. J. Salisbury's address to Section K (Botany), which one member described as "short, simple and lovable". They were also supported by speakers at a later discussion on the

educational function of a university. Prof. F. A. E. Crew's presidential address was regarded as one of the most stimulating of the whole meeting. It was, however, in Section A that records were broken in an extraordinary manner by Dr. G. W. C. Kaye. Here, for the first time, a president took acoustics as the subject of his address, and delivered it, appropriately enough, in a lecture theatre designed by Prof. E. H. Barton just before his death. Moreover, the address was for the first time illustrated by experiments, in which a selection of some forty motor-horns were used with great effect to produce another record in noise. Perhaps it was the general appeal of the subject which caused Section A to be crowded out and to provide a further record in the nature of a repeat performance of the experiments later in the day. Section A must also be credited with another record, which it certainly did not seek; one of its most pleasant social activities appeared in the programme under the heading "mystery trip".

The general discussions had clearly been well planned. Dr. F. L. Pyman's presidential address to Section B opened a stimulating symposium on various aspects of chemotherapy, while, at the same time, local geologists, headed by Prof. H. H. Swinnerton, had the pleasure of describing the geology of the Nottingham district to Section C.

Section A enjoyed a general discussion on the mode of action of the photographic plate, in which a theory of latent image formation put forward by Prof. N. F. Mott was closely followed. Sections A, B and I gathered to hear a useful symposium on surface action in biology initiated by Dr. Irving Langmuir. Prof. D. Brunt added much interest to a discussion of the upper atmosphere by releasing a sounding balloon, carrying a Dines meteograph to record the pressure and temperature at different stages of its ascent, and a ten-shilling note with an I.O.U. for a like sum to ensure its return. The balloon was released in the College grounds on Monday morning in the presence of an enthusiastic crowd. Less spectacular, but of considerable interest to local members, was the joint discussions of Sections C and E on the potential mineral resources of Nottinghamshire and Lincolnshire and their geographical significance. Perhaps the star turn in the joint discussions was the meeting of Sections C, D, E, F, K and M on Tuesday evening to talk about planning the land of Britain.

There can be no doubt that from a scientific point of view the Nottingham meeting was an unqualified success. From a social point of view it was equally pleasant. The excellent hostel accommodation, situated so close to the College and in the same beautiful surroundings, contributed greatly to the happiness of visiting members. The civic reception was obviously thoroughly enjoyed by guests and hosts alike, the flood-lit gardens of the Castle being much admired. Works visits, garden parties and excursions were heavily booked. Local firms and industrial undertakings were most generous in entertaining the Association. At the same time, the extraordinarily fine series of cinema films on subjects of biological interest, shown to members in the Savoy Cinema, proved to be a great attraction.

Forty-four years is the interval of time between the last two visits of the Association to Nottingham; it is to be hoped that, both on scientific and social grounds, the Association will not wait another forty years before it returns.

On September 3 the General Committee adopted the nomination of the Council of Lord Rayleigh to succeed Sir Edward Poulton as president of the Association. The General Officers will continue to be Prof. P. G. H. Boswell as General Treasurer and Prof. F. T. Brooks and Prof. Allan Ferguson as General Secretaries. The new members of Council are Prof. T. S. Moore, Mr. R. S. Whipple, Prof. H. J. Fleure, Prof. J. G. Smith and Prof. J. C. Philip.

Future places of meeting of the Association are Cambridge (Aug. 17-24, 1938) and Dundee (1939). Invitations have been received for the Association to meet in Swansea in any convenient year, in Belfast in 1941 or any year nearly following, and in 1943 in Birmingham.

Under the arrangement proposed last year by the Council and adopted by the General Committee, the British Science Guild was incorporated into the Association as from November 30, 1936. In accordance with the agreement of incorporation a British Science Guild Committee has been appointed to continue arrangements for lectures already initiated by the Guild, and for any others of similar character which may be approved by the Council. The first of the lectures arranged by the Association under the above scheme was the Alexander Pedler lecture, given in Leicester on May 3, in co-operation with the University College in that city, by Prof. Allan Ferguson. The first Norman Lockyer lecture to be so arranged will be given by Dr. R. E. Mortimer Wheeler in the Goldsmiths' Hall, London, by kind permission of the Goldsmiths' Company, on November 24.

The first of the triennial lectures under the foundation of Mr. G. Radford Mather will be given by the Rt. Hon. J. Ramsay MacDonald, M.P., F.R.S., in the Royal Institution, London, by kind permission of the managers, on October 22.

The Council records with much satisfaction that Lord Rutherford has accepted the presidency of the joint Congress of the Indian Science Congress Association and a delegation from the British Association in January next.

Obituary Notice

Prof. F. C. S. Schiller

PROF. F. C. S. SCHILLER, who died in Los Angeles on August 7 after a long and lingering illness, was born in 1864, the son of Ferdinand Schiller of Calcutta. He was educated at Rugby and Balliol, and graduated in the first class of Literæ Humaniores, winning later the Taylorian scholarship for German in 1887. For a few years (1893-97) he

occupied the post of instructor in philosophy at Cornell University. Then in 1897 he returned to Oxford, and became fellow and tutor of Corpus, where he remained for more than thirty years. His former pupils speak of him as a decidedly stimulating and suggestive teacher, who, although out of touch with the types of philosophical theory prevalent in Oxford, exerted considerable influence there as an

acute critic and searcher after truth. He was president of the Aristotelian Society in 1921, and had from 1906 onwards contributed to its *Proceedings* a large number of papers. At philosophical gatherings he was a well-known figure; he read, for example, a paper at the International Congress of Philosophy, held at Harvard in 1926. To *Mind* he was a frequent contributor, and was for many years treasurer of the *Mind* Association. In 1926 he was elected a fellow of the British Academy. In 1929 he was appointed visiting professor in the University of Southern California, and was accustomed latterly to spend half of each year in the United States and half in England.

Schiller's student life in Oxford began immediately after the death of T. H. Green, but from the outset he was out of sympathy with Green's idealism. In his earliest book, "Riddles of the Sphinx", published under the pseudonym "A Troglodyte" in 1901 (2nd edition, revised, with the author's own name, in 1904, new edition 1910), Schiller followed largely in the line of the evolution theory, as expounded by Darwin; and developed at some length a view, not unlike that of J. S. Mill, of God as a finite individual, immanent in the world as a living activity, but transcendent as a true personality. In the following year, in 1902, the volume entitled "Personal Idealism" appeared, containing contributions from eight members of the University of Oxford; Schiller's essay therein was on "Axioms as Postulates", and in this essay he outlined for the first time the position which, following William James, he designated as that of 'pragmatism', or later 'humanism'.

Truth, Schiller maintained, is *human truth*, and is incapable of coming into being without human effort and agency. Human action is psychologically conditioned; consequently, the concrete fullness of human interests, desires, emotions, satisfactions, purposes, hopes and fears is relevant to a theory of knowledge and must not be abstracted from. The world of our experience is not a ready-made datum; it is essentially what we make of it. Fruitless, therefore, is it to attempt to define it by what it was originally or by what it would be apart from us; it is what is made of it. Accordingly, the world is *plastic* and may be moulded by our wishes, if only we are determined to give effect to them, and are content to learn from experience, that is, by trying *by what means* we may do so. The principles we employ in such construction are, it was urged, in the beginning *demands* we make upon our experience, postulates or hypotheses, "starting-points and stepping-stones". Of these, when tried, many have to be abandoned; others remain precarious, and more or less 'matters of faith'; only a few rise to be unquestioned axioms. The "making of truth" is thus, it was contended, in a very real sense also a "making of reality". For in validating our claims to 'truth' we really 'discover' realities; and we virtually *transform* these by our cognitive efforts, thereby proving our desires and ideas to be real forces in the shaping of our world.

Perhaps Schiller's chief contribution to the thought

of his time is to be found in his sustained insistence on the way in which principles, even those which appear to be the most self-evident and fundamental, are in point of fact tentative, and require to be tested by their success or want of success in enabling the investigator to get into touch with natural events; and in the repeated emphasis which he laid on the manner in which apparent facts receive modification through the growth of science. Furthermore, that man is not to be separated from Nature, and looked upon as a mere observer of a series of events which he can do nothing to alter, that revaluation and not static finality is a main feature of any truth discoverable by man—these are certainly points which it was worth while to emphasize; and upon them Schiller was constantly laying stress.

In addition to the works already referred to, Schiller was the author of "Humanism", 1903 (2nd edition 1912), "Studies in Humanism", 1907 (2nd edition 1912) and "Plato or Protagoras", 1908. He wrote also two books on logic—one, "Formal Logic: A Scientific and Social Problem", 1912, which was a sustained attack on what he regarded as the futility, the verbalism, the self-contradictoriness of the traditional logic; the other, which was a more constructive work, "Logic for Use", 1929. In the latter the logic which he desiderated was not the logic of proof but the logic of discovery, and he has said probably wellnigh everything there is to say on this subject. Nor must one omit to mention the two contributions he made to Singer's "Studies in the History and Methods of Science", on "Scientific Discovery and Logical Proof" in vol. 1 (1917) and on "Hypothesis" in vol. 2 (1921). G. D. H.

We regret to announce the following deaths:

Prof. Hendrik Aldersloff, director of the State Serum Institute at Utrecht, president of the Dutch Society for the Advancement of Medicine, editor of the *Tijdschrift voor Sociale Hygiëne*, aged sixty years.

Prof. P. W. Cloessen, professor of biology in Cornell University, known for his work in economic entomology, on August 16, aged fifty-one years.

Prof. J. E. Duerden, who was associated with the Wool Industries Research Association, Torridon, Headingley, Leeds, and formerly professor of zoology in the Rhodes University College, Grahamstown, on September 4, aged seventy-two years.

Prof. Albert Heim, For. Mem. R.S., formerly director of the Geological Museum and Swiss Geological Survey, Zurich, on September 1, aged eighty-nine years.

Prof. M. Maclean, emeritus professor of electrical engineering in the Royal Technical College, Glasgow, on September 2.

Prof. Pietro R. Pirotta, formerly professor of botany in the University of Rome, on August 4, aged eighty-three years.

Mr. F. C. Thompson, lecturer in the Department of Leather Industries in the University of Leeds, aged forty-six years.

News and Views

The Right Hon. Lord Rayleigh, F.R.S.

THE British Association holds its annual meeting in Cambridge in August 1938, and the General Committee of the Association has elected Lord Rayleigh to the presidential chair for that meeting in succession to the veteran biologist Sir Edward Poulton. Readers of NATURE need little introduction to Lord Rayleigh, whose influence on the development of physical science has been so potent and so profound. First and foremost an experimental physicist, he has his father's flair for recognizing those aspects of an experimental investigation which most need stressing, and for extracting results of fundamental importance from apparatus of simple, even primitive, type. His work on radium and the earth's heat is classic in quality, and he has elucidated many diverse, and yet related, phenomena in his studies of the aurora borealis, the light of the night sky, the green flash, and the fluorescence of mercury vapour. He has lately studied the conditions of optical contact of glass surfaces, and has investigated, by admirably simple methods, the pull required to separate, and the work done in separating, contacted surfaces. He has measured the small amount of reflection between two contacted glass surfaces, and has shown that the blackness of the black centre of the Newton's rings formed between a spherical and a plane surface is by no means perfect.

LORD RAYLEIGH'S services to science on the administrative side are equally varied and weighty. He is chairman of the governors of the Imperial College of Science and Technology, and of the executive committee of the National Physical Laboratory. He had filled the offices of foreign secretary of the Royal Society, of president of Section A of the British Association, and of president of the Physical Society. Lord Rayleigh's contacts with Cambridge are many, and make the choice of the General Committee a singularly happy one. The nature and scope of his address remain to be seen, but, whatever be his choice, the scientific world, and indeed, the world at large, may look forward to receiving a pronouncement of fundamental importance.

Grass and the Nation's Food Supply

DR. R. E. SLADE'S evening discourse at the British Association, delivered on September 3, came well within the category of scientific contributions bearing upon social welfare, for it demonstrated the physical possibility of greatly increasing the nation's home-grown food supply, and incidentally of improving soil fertility and of helping to put the much-suffering farmer upon his financial feet. A conspicuous feature of recent agricultural progress has been the recogni-

tion of grass as a crop, and how by good management and the use of scientific methods of grass conservation, the productivity of pastures can be immensely increased. Early researches on grass as a food for stock were largely confined to hay, and though this form of 'bottled sunshine' is unlikely ever to disappear, the nutrients in grass can be best conserved either as ensilage or as artificially dried grass. No system of cultivating grassland can be adequate unless it takes cognizance of the reaction between the pasture herbage and the grazing animal, for by controlling the time and intensity of grazing or cutting, by judicious manuring, and by timely cultivations, a succession of palatable and nutritious herbage can be maintained throughout the grazing season, and this season can be extended at both ends, that is, in spring and in autumn. The re-discovery by Prof. T. B. Wood and Dr. H. E. Woodman of the high feeding value of leafy, young grass, and the breeding of leafy and highly nutritious strains of indigenous grasses by Prof. R. G. Stapledon and his co-workers at Aberystwyth, have opened up a vista of great possibilities for home agriculture and national food supply.

As an example of what can be done to improve the yield of food material from grassland, Dr. Slade described the results of a highly interesting experiment that has been carried on since 1935 at a large dairy farm near Middlewich, in Cheshire, where the climate is favourable and the management has been scientific as well as practical. Monthly records of milk production and live-weight increase of animals have been recorded throughout, and from these data the amounts of food (protein and starch equivalents) provided by the grass and the hay have been calculated. The average yield of crude protein per acre in 1935 and 1936 was 640 lb., which is three to four times as much as that given by an average pasture in Great Britain. Equally good results have been obtained on a 'farmer's farm' near Middlesbrough, in Yorkshire, over a period of ten years, and it was suggested that yields of crude protein up to 1,500 lb. per acre should be obtainable when Prof. Stapledon's new strains of indigenous grasses become available. A yield of 700 lb. protein per acre is equivalent to a yield of 45 lb. protein as dressed beef, or to 103 lb. protein as milk, which is just about the amount of protein provided for human food by an average acre of wheat. Pigs fed on grass protein could provide 70 lb. of pork per acre of grassland, but for this purpose the grass would have to be defibrinated. What is needed, and what seems feasible, is a protein-rich food made from grass deprived of its fibre, a kind of 'grass cheese', which could be fed to pigs for producing pork, and in times of national emergency could be eaten by the people.

Science and Progress

THE address, "Science in Everyday Life", given at Long Eaton on September 7 in connexion with the Nottingham meeting of the British Association by Dr. J. E. R. Constable, dealt with the more popular side of the activities of the Department of Scientific and Industrial Research and the laboratories engaged in research under its auspices. The National Physical Laboratory has, for example, fostered the use of X-rays for the detection of internal defects in steamship and aeroplane propellers, in almost all types of industrial products and in human teeth, and of foreign bodies in packed foods. It has also undertaken the measurement of noise and suggested methods of diminishing noises in buildings by the use of sound-absorbing devices. The Fuel Research Station has been investigating the best methods of getting the most heat and the least smoke from coal, while the Food Investigation Board has been finding out the best methods of keeping foods of all kinds in cold storage for long periods without its deteriorating.

ANOTHER branch of the activities of the Department to which Dr. Constable referred was that of the Road Research Laboratory, which is determining the best methods and materials for the construction of roads with good wearing qualities and non-skid surfaces. Machines for measuring the durability and non-skid property of sample roads and for determining when a road surface must be condemned as bad have been constructed and are giving valuable information. Closely associated with this laboratory is that for building research, which has succeeded in solving some of the difficulties in the production on a large scale of uniformity in structural materials such as concrete, and in the preservation of the stonework of buildings, and has investigated the best methods of dealing with many of the newer quick-setting plasters and cements. As a result of the work of the laboratory the smoking chimney need no longer be tolerated.

Dr. R. d'E. Atkinson

DR. R. d'E. ATKINSON has been appointed chief assistant in the Royal Observatory, Greenwich. Dr. Atkinson obtained a first class in the Physics Final Honour School in Oxford in 1922 and was elected to a research fellowship at Hertford College. In 1926 he obtained a Rockefeller travelling fellowship and studied in Göttingen for two years under Prof. Franck, taking the D.Phil. degree. After a short period as demonstrator in the physics laboratory of the Technische Hochschule in Berlin-Charlottenburg, he was appointed assistant professor and, in 1933, associate professor of physics in the Rutgers University, New Brunswick. Dr. Atkinson has published many papers. Of particular interest is his work on atomic synthesis and the source of stellar energy, in the course of which he deduced, before the discovery of the neutron, from general considerations of atomic abundance in the sun and stars, that there must be some type of particle that could penetrate a highly charged nucleus more easily than a proton.

Charles Bouchard (1837-1915)

CHARLES JACQUES BOUCHARD, a distinguished French physician, was born on September 6, 1837. He studied medicine first at Lyons and then in Paris, where he became house physician to Charcot, with whom he afterwards collaborated in the study of certain nervous diseases. He is best known for his works on the pathology of cerebral hemorrhage (1866) and autointoxication (1887), both of which were translated into English, and the diseases caused by diminished nutrition (1870-80). He was also co-editor of a system of medicine with Charcot and Briassaud (1891-94) and of a treatise on general pathology in collaboration with H. Roger (1895-1903). In 1887 he founded the *Revue de la Tuberculose* with Verneuil, and in 1899 the *Journal de Physiologie et de Pathologie Générale* with Chauveau as his co-editor. Bouchard was one of the first physicians in Paris to take an interest in radiology, and installed a radio-scopic apparatus at his own expense for the examination of his patients at the Charité hospital, where he was physician. In addition to occupying the chair of general pathology and therapeutics in the Paris faculty of medicine (1877) his distinctions included the presidency of the second French Congress of Medicine (1895), Société de Biologie (1896) and Academy of Sciences (1908). His death took place on October 28, 1915. The work entitled "Un Médecin Philosophe: Charles Bouchard, son œuvre et son temps", by Paul Legendre (1924), forms one of the outstanding medical biographies.

Trades Union Congress and Science

THE announcement made by Mr. Ernest Bevin in his presidential address to the Trades Union Congress meeting at Norwich of the formation of a scientific advisory council will be widely welcomed. Mr. Bevin paid tribute to the progress that science has made, but pointed out that society has not kept pace with it in making the fundamental readjustments and assimilating the results of research, discovery and invention. The General Council of the Congress believes that men of science can make a further contribution to progress by assisting such a movement as the Trades Union Congress with counsel and knowledge. It has accordingly decided to establish a Scientific Advisory Council, the purpose of which will be to enable the Congress and its constituent unions to secure the help and advice of leading scientific workers in some systematic and regular way. "The General Council are convinced that their prevision and foreknowledge of the significance of scientific discovery in all fields of research would be of incalculable value not only to the trade union movement, but to the community." Mr. Bevin gave a warning that this does not mean that scientific workers are to be invited to frame the policy of the Congress; the General Council wishes to be in touch with representative men of science by means of such an advisory council and panels of scientific workers, from which it will be able to obtain information and advice in dealing with its own problems. It would

clearly be to the advantage of both science and labour if the Congress were represented upon research boards and research associations concerned with industrial developments. The human factor in industrial progress has often been neglected in the past, and by bringing representatives of labour into close association with scientific and inventive work, the degrading results of some of their past applications to industry may be avoided.

Racial Doctrine

A NEW periodical publication with the title *Races et Racisme* is devoted to the record of current development in the application of theories of race to the doctrine of nationalism, with special reference to Germany (office of publication, 47 rue de Miromesnil, Paris VIIIe, price 1 fr.). Its main object is to keep the French people abreast of the progress of a movement of supreme importance in the world of to-day, upon which, it is thought, they are not sufficiently well informed. It should also prove valuable to those who desire first-hand and trustworthy information in readily accessible form of the increasing restrictions and penalties which are being imposed on freedom of thought and scientific and intellectual development in the nationalist-socialistic State. The utility of such a publication must clearly depend upon its freedom from the taint of the selective activity of the propagandist. The names which appear on the lists of the Comité de Patronage and the Comité Directeur are a guarantee that an objective impartiality will be exercised in the selection of material for publication. The lists include such well-known names as M. Gabriel Hanotaux, Prof. Lucien Lévy-Bruhl, Prof. Paul Pelliot, Prof. G. Bouglé, P. Maurice Léonardt, le Comte Jean de Pange, and Prof. Paul Rivet, with Prof. E. Vermeil as one of two secretaries. *Races et Racisme*, of which numbers will appear at two-monthly intervals, will represent the trend of German thought in racial doctrine by verbatim reports, or full abstracts, of official documents, new laws and regulations, official pronouncements, articles and speeches of authority, as well as by analyses of books and a record of relevant events—all, as a rule, without comment, except when further explanation is considered necessary.

AN example of the commentary which the editorial body considers appropriate is afforded by the opening article, which runs through the two numbers before us and is still in progress. This is an exposition of the development of racial ideas in Germany by M. Edmond Vermeil. It begins with Leibniz and Herder and the concepts of the eighteenth century, and shows how the Germanic idea has progressed from the universalism of the philosopher to the Pan-Germanism upon which the doctrine of 'race' and 'blood' has been engrafted to implement Hitlerian nationalism. M. Vermeil, who takes a broad and philosophic view of his subject, will, in his later instalments, demonstrate how and why what appears to be no more than a political manoeuvre, when judged by its objective, must necessarily permeate and transform

activities, apparently remote from the political arena when functioning freely, to produce 'German' art, a 'German' science and a 'German' religion. It is to be noted, however, that the sweeping official claims for purity of race and the coincidence of Nordic and Aryan are so far abandoned that Prof. Oswald Kron of Tübingen is permitted to say that there are five or six races among the German people, while he claims for them a psychological unity.

Native Lands in South Africa: A "New Deal"

CONSIDERABLE progress has been made in the provision of additional reserves for the native population of South Africa since the passing of the Native Lands Act, which was promulgated in August, 1936. Up to July last, according to a dispatch from the Cape Town correspondent of *The Times*, which appears in the issue of September 3, £800,000 has already been spent on the purchase of farms from Europeans. The farms which have been bought up to the present are mostly situated in the Transvaal, where the need for native land is greatest, as this is the principal area of native location on European farms, a practice which will not be permitted in future. The land is being allotted to the natives and settlement will proceed as the present European holders vacate. They have been permitted to remain in possession until after their harvest, and land is being provided for them elsewhere. Under the provisions of the Native Trust and Land Act, 1936, the South African Native Trust, representing the Government, is authorized to acquire 7,250,000 morgen (about 15,000,000 acres) of lands for native use. It is anticipated that the work of settling the native on these lands, which will now go on steadily, will occupy a period of several years. It is clear, however, that if the situation is not taken in hand drastically, and the conditions which prevail on native lands, not only in South Africa, but also in territories to the north, are allowed to continue unchecked, a situation similar to that for which the present measures are intended to be a remedy will again arise before many years have passed, and probably then be more difficult to meet.

THE present deplorable condition of the existing native reserves and the agitation and discontent to which the shortage of native lands has given rise is not entirely due to overpressure of population, though this has been an important factor. Traditional methods of native agriculture and grazing, of which the ill effects were negligible when a practically unlimited area allowed freedom of movement and gave exhausted soil an opportunity to recover, have led, under the system of European restriction of boundaries and suppression of tribal raids, to a general impoverishment of the land, which has further deteriorated through the erosion consequent on the overstocking which follows from the Bantu regard for cattle as a sole and almost sacrosanct form of wealth. Since the passing of the Act, the Native Affairs Commission has been busily engaged in framing a policy which is intended to remedy these

adverse conditions. Regulations and remedial measures are to be applied to the existing reserves, such as fencing, irrigation, parcelling out the land for occupational and agricultural use, as well as for rotational cropping and the like, by which it is hoped to introduce into native tribal custom a more economical use of the land. On the new reserves agricultural officers will be appointed to instruct and, if necessary, discipline the natives in modern methods of cultivation. The educational process is bound to be slow; and its success, as previous experiments have shown, will depend very largely upon the discretion with which new methods are welded into traditional custom.

Physics and Society

IN an address before the American Physical Society, Washington, on April 30, on Science and Society (*J. Applied Phys.*, 8, 373; 1937), D. Sarnoff, president of the Radio Corporation of America, referred to the relation of the physicist to the far-reaching social changes which follow his discoveries. The radio industry had its origin in the purely theoretical reasoning of Clerk Maxwell when in 1865 he advanced reasons for the existence of electromagnetic waves, although it was only in 1895 that Marconi gave the world a practical system of wireless telegraphy. Already 150 social effects have been traced directly to radio, and the end is not yet in sight. The major obstacles to the public introduction of television no longer lie in the field of research and engineering. The creation of a new art form has demanded new techniques of writing, direction and studio control. Here as elsewhere a scientific approach to the solution of human problems is required, and it is essential that mankind should learn how to use the assets which are the product of the scientific mind. Civilization depends for its advance upon our expanding knowledge of the social as well as of the physical sciences, for no society can solve its problems by intuition or rule of thumb. The advance of social science no less than that of physical science, calls for the creative imagination of a Newton and a Maxwell, an Edison and a Marconi. Obsolescence is a factor in social as well as in industrial machines.

THE social investigator must approach the problems of society in the clear light of an unbiased mind. He must collect and analyse facts, seek to fathom causes and establish principles, which he must always be willing to reconsider in the light of results. The permanent advance of society depends on our following procedure similar to that of the experienced surgeon. We must not be afraid to operate but must know when a less spectacular and safer treatment will be adequate. Social and economic facts must be investigated, verified and analysed, and the analysis and conclusions disseminated widely by popular education and debate. Industry is continually entering new realms of knowledge, and close understanding and co-operation are required between its leaders and the investigators in the universities.

Industry which has not learnt to employ scientific workers is doomed. Moreover, the problems created by technical science can only be solved by increasing and applying our knowledge of social science, and Mr. Sarnoff urged that the immediate goal of social science should be to achieve economic justice, peace and prosperity in a free democracy. Because that involves collective effort, it does not mean the suppression of individual liberty. Freedom of the individual is essential to the full expression of his creative faculties. Science and society depend upon each other, and when the basic lesson of science, that knowledge of the truth without fear or prejudice is indispensable to progress, is rejected, science—and society with it—goes backward instead of forward.

Education and Training for the Oil Industry

THE days when a liberal education and an effective personality were sufficient qualifications for entry into the petroleum industry are now over. As Prof. A. W. Nash pointed out in a paper presented to the Chemical Engineering Congress, World Power Conference, 1936 (*J. Inst. Pet. Tech.*, 22; 1936), specialized vocational training is the only adequate background for technical men seeking employment in the industry. Moreover, this specialized training should be directed towards one particular branch of the industry, for example, geology, production, or refining, for in each of these branches different sciences are involved and correspondingly different technical knowledge is necessary for the solution of such problems as may be encountered. Before proceeding to specialize, however, the student must acquire a sound knowledge of the fundamental principles of physics, mathematics and chemistry, together with a working understanding of engineering and chemical engineering. Finally, having mastered these fundamentals and specialized in a particular branch of the industry, the technician should familiarize himself at least with the basic principles underlying the remaining branches of the industry, for in this way alone will he acquire a clear conception of any problem which may present itself from the point of view of the industry as a whole. Universities and other institutions which provide such training for the industry, are fully alive to the fact that, apart from the actual acquisition of knowledge, the student is there primarily to learn how to apply such knowledge, to interpret it and make use of it in the solution of new problems, and their curricula are adjusted accordingly. For the man who has made full use of any such training, there are openings in the industry unrivalled in any other from the points of view of scope and advancement.

The Spread of the Sahara

THERE is abundant evidence that early in the Quaternary age the Sahara was inhabited by man and that desiccation has since been proceeding. In so far as this process is one of climatic change, it is beyond the control of man; but there is also much evidence that the increase of desert conditions in both north and south is largely due to human interference.

In a pamphlet entitled "The Threat of the Sahara", reprinted from the *Journal of the Royal African Society*, Prof. E. P. Stebbing reviews the available evidence of progressive desiccation and discusses the causes. These can be summarized as war, primitive methods of agriculture, excessive grazing and pasturage and fire. Intertribal warfare has laid waste great tracts and so promoted soil erosion. The method of shifting cultivation, entailing the cutting down of successive areas of forest and their abandonment when annual burning produces too poor a supply of fertilizing wood ash, has allowed the spread of scrub land. This degraded forest is given over to pasturage which tends to destroy the vegetation, the last stage in its use being the pasturing of goats. Prof. Stebbing sees little evidence that the desiccation can be attributed to climatic oscillations, and is extremely doubtful that the succession of a wet period will reverse the present trend.

The Zoological Society of Scotland

THE increase in the number of visitors to the Zoological Park near Edinburgh to just short of half a million, and a surplus on the year's working of £1,708, indicate the material success of this Society (*Ann. Report Zoo. Soc. Scot.*, 1936-37). In other ways it has made notable progress. The new open-air enclosure for tigers, which occupies the site of an old sandstone quarry, is a most striking example of the use of natural rock, and a new restaurant, made necessary by the increase of visitors, has been completed and opened. During the year five king penguin chicks were hatched, of which three were successfully reared, and amongst mammals there were born and reared lion cubs, four beavers, three llamas, a nilghai and Barbary sheep. The chimpanzee born in January 1936 has developed well, and for many years the breeding of tropical freshwater fishes has been a feature of the Carnegie Aquarium. A successful innovation was the holding of a series of meetings of members at which lectures upon, and illustrated accounts of, their investigations of animal habits and behaviour were given by experts.

Survey of India

IN 1905 the hope was expressed by the Survey of India that in twenty-five years maps of the whole Indian Empire on a scale of one inch to a mile would be available. The Annual Report for 1936 (Calcutta, 2s. 6d.) points out that this hope is far from realization, and that a little more than half the area is now mapped on that scale. When it was realized in 1913 that the scheme could not be completed for many years, it was decided to reduce the scale of survey for the less populous areas. As a result, two-thirds of the country is now covered by modern maps ranging in scale from one inch to a quarter inch. In the year under review more than fifty-three thousand square miles was surveyed, in addition to a certain amount of revision. The report contains full index sheets to all the scales, including the sheets of the Carte Internationale on a scale of one million which cover India and adjoining lands.

Motor-boat Speed Record

ON September 1, Sir Malcolm Campbell, driving his new motor-boat *Bluebird* on Lake Maggiore, made two runs over a measured mile at an average speed of 203.3 km. an hour. His boat is equipped with a single Rolls-Royce engine of 2000 h.p., similar to that of his motor-car *Bluebird*. Sir Malcolm has thus achieved the distinction of holding the speed record for both land and water.

Announcements

MR. J. D. GRIFFITH DAVIES, an administrative assistant in the Higher Education Department at Leeds, has been appointed assistant secretary of the Royal Society as from September 1 in succession to Mr. R. Winckworth, who at his own request has reverted to his previous position in charge of the Society's publications.

THE following appointments and promotions have recently been made in the Colonial Service: E. F. Allen, to be agricultural officer, Malaya; D. B. Fanshawe, to be assistant conservator of forests, British Guiana; D. E. Faulkner, to be veterinary officer, Gold Coast; K. D. S. MacOwan, to be veterinary officer, Kenya; J. W. Ewart, to be assistant curator of gardens, Malaya; F. R. Mason (agricultural field officer, Malaya), to be deputy director, Department of Agriculture and Fisheries, Palestine; R. W. R. Miller (director of science and agriculture, Barbados), to be director of agriculture, Zanzibar; W. D. MacGregor (senior assistant conservator of forests), to be conservator of forests, Nigeria; H. G. Wiltshire (pathologist, Zanzibar), to be senior pathologist, Uganda; W. Horsfield (staff surveyor), to be district surveyor, Lands and Mines Department, Tanganyika; H. M. Pendlebury (curator, Selangor Museum), to be director of museums, Federated Malay States; J. L. Tetley (assistant analyst, Imports and Exports Department, Hong Kong), to be chemist, Institute for Medical Research, Federated Malay States.

DR. ROBLEY D. EVANS, assistant professor of physics at the Massachusetts Institute of Technology, recently received the first Theobald Smith award in medical science, consisting of a bronze medal and one thousand dollars, for his researches, which have led to a method of detecting radium poisoning before its fatal stage and a treatment for extracting radium from bones.

A USEFUL little volume on most aspects of map-making has been published under the title of "Cartography" (Special Publication No. 205. U.S. Dept. of Commerce. Coast and Geodetic Survey 1936. 60 cents). The pamphlet opens with a short historical survey, after which is a discussion of different kinds of maps and charts and their requirements. Then follows a chapter on compilation of the material for a map and a clear, though brief, account of the chief projections. The last section treats of the technique of construction. There are many reproductions of sections of various maps, American and others.

Asymmetry in Metals of Hexagonal Structure

THE axial ratio, c/a , of the majority of metals having a hexagonal close-packed type of structure differs appreciably from the value $2\sqrt{2}/3 = 1.633$ which corresponds to a hexagonal close-packed system of spheres. The two most notable deviations are for zinc and cadmium, for which $c/a = 1.86$ and 1.89 respectively, while for beryllium, titanium, zirconium, hafnium, yttrium, ruthenium and osmium, c/a lies between 1.58 and 1.59 . These facts have sometimes been expressed by describing the atomic domains as having the forms of prolate and oblate spheroids when c/a is respectively greater than and less than 1.633 ; but it is only recently that experimental evidence has been obtained which throws light on the nature of the asymmetry in these metals.

X-ray measurements for zinc¹ and cadmium² have shown that the atomic vibrations in these metals are markedly asymmetric, the mean atomic displacement along the hexagonal axis, the c -axis, being greater than normal to the axis; this suggests that the high values of the axial ratios arise partly, if not wholly, from the asymmetric character of the vibrations. This is further supported by X-ray measurements by us for magnesium³, similar to the previous experiments on zinc and cadmium, which indicate that the lattice vibrations in magnesium are much more nearly isotropic; this may be correlated with the fact that c/a for magnesium is 1.624 , which approximates closely to the ideal value, 1.633 .

Results have recently been obtained, however, indicating the existence of an appreciable atomic asymmetry. It was first pointed out by one of us⁴ (G. W. B.), that the $(10\bar{1}0)$ reflections from zinc and cadmium give abnormally high scattering factors compared with the adjacent reflections, and since these reflections occur at small angles for which lattice vibration has relatively little effect, it was thought that it might be an indication of atomic asymmetry. This has since been confirmed in the case of zinc by Jauncey and Bruce⁵, who also have accepted it as evidence for atomic asymmetry, and by other workers in Jauncey's laboratory⁶; Wollan and Harvey⁷ especially have carried the matter a step further by making measurements at two temperatures. In the light of this evidence, it appears well established now that the atoms in metallic zinc and cadmium are asymmetric and are more diffuse along the c -axis than normal to it.

We have recently investigated ruthenium, a hexagonal metal with $c/a = 1.58$, which has provided evidence for a different type of atomic asymmetry. The lattice vibrations at room temperature are relatively small, so that this metal is particularly suitable for studying atomic asymmetry. The X-ray scattering factors of ruthenium are shown in Fig. 1, the length of the line attached to each reflection indicating

the possible experimental error. Among the lower order reflections, 2 and 5 are well above the mean curve and 1, 3, 4 and 6 fall either on or below the curve, depending on how it is drawn. The indices of the reflections are given in the key attached to the figure. The curve is extrapolated to 42.8 at $(\sin \theta)/\lambda = 0$, which is the atomic number, 44 , less a dispersion correction of 1.2 . An interesting feature of these results is that whereas the second reflection

Fig. 1.

X-RAY SCATTERING FACTOR OF RUTHENIUM

1, $10\bar{1}0$	4, $10\bar{1}2$
2, 0002	5, $11\bar{2}0$
3, $10\bar{1}1$	6, $10\bar{1}3$

comes from the basal plane, the fifth reflection, which is also high, comes from a plane parallel to the c -axis, that is, normal to the basal plane. Evidently, then, a simple extension of the atoms either in the direction of the c -axis or in the basal plane will not explain these results.

An explanation is obtained, however, if we suppose that there is a concentration of electron density having its centre of gravity at the mid-point of every triangle formed by three atoms in the basal plane, as in Fig. 2, where the black circles represent the atoms and the clear circles the additional electron density. It is seen that the additional charge lies between planes of the type $(10\bar{1}0)$, $(10\bar{1}1)$, $(10\bar{1}2)$, etc., corresponding to reflections 1, 3, 4 and 6, and so gives low

scattering factors, but lies on planes of the type $(11\bar{2}0)$ and also on the basal plane (0001) , the plane of the diagram. As to why there should be a concentration of electron density, which need only be of the order of 1-2 electrons to account for the observations, we cannot yet say; but it may perhaps be due to the overlapping of the wave-functions of the incomplete $4d$ shell, which for ruthenium have a considerable spread. An objection to this simple

Fig. 2.

explanation is that it would require concentrations of electron density at other points in the lattice which would not agree with the present observations. Whatever may be the ultimate explanation, however, the experimental results point strongly to a concentration of electron density of the type indicated in Fig. 2.

A New Equilibrium Diagram for the System Fe—C

Two equilibrium diagrams, the single diagram and the double diagram, have been proposed for the system Fe—C and we cannot, as yet, decide upon which is the correct one. The single diagram assumes that graphite never separates directly from molten iron, which was, however, recently experimentally disproved by different workers including myself. It meets with a second difficulty as it represents a metastable equilibrium; but a stable diagram for such an important alloy as Fe—C is required.

The double diagram indicates that graphite may sometimes be formed directly from the melt; it is free from the above difficulties, but it encounters more as follows:

(1) Two diagrams (stable and metastable) are drawn with an interval less than 10°C ., and such a coupled diagram makes the matter difficult to understand. Several double diagrams have been proposed by different authors, and it is extremely difficult to choose from them.

(2) Two eutectic temperatures (austenite-cementite and austenite-graphite) are expected by the double diagram, but many authors have been able to find only one.

(3) The lower (metastable) lines of the double diagram express a super-cooling. We have now about 400 binary equilibrium diagrams and only three of them, Cd—Sb, Cd—As, Fe—C, include super-cooling. Super-cooling in the systems Cd—Sb and Cd—As is abnormal. Ordinary super-cooling is added only in the double diagram of Fe—C, which is unreasonable. We must have important reasons to justify the addition of super-cooling in the diagram, and the metastable equilibrium lines added should have been clearly proved by experiment; but neither condition is fulfilled. The double diagram includes the super-cooling at the eutectic but not that at the eutectoid (martensite formation is never included). This, again, is a self-contradictory feature of the double diagram.

Fig. 1.

NEW EQUILIBRIUM DIAGRAM. LOW TEMPERATURES:
STABLE EQUILIBRIUM Fe—C; HIGH TEMPERATURES:
STABLE EQUILIBRIUM Fe—Fe₃C.

Fig. 1 shows a new equilibrium diagram. Super-cooling is omitted, thus avoiding all the difficulties of the double diagram. It shows a stable equilibrium, assuming Fe₃C to decompose on solidifying or on separating from austenite, eliminating the two difficulties of the single diagram.

The details will be published in the report of this Institute.

Diffraction of Slow Positive Ions

AN experimental method has been developed which permits photographic recording of the scattering of slow positive ions through angles of a fraction of a degree. This is accomplished by using a very fine, electrostatically focused incident beam and accelerating the ions, *after the scattering*, to a velocity high enough to affect a photographic plate. The high-voltage electrostatic lens used to give the acceleration also produces an angular magnification of the scattered rays.

Fig. 1 shows the scattering of lithium ions by a jet of sodium vapour, photograph *a* for 292 volt ions, *b* for 149 volt ions. Around the central spot is a sharply defined disk of nearly uniform intensity, having an angular radius of 0.0083 radians for the faster ions and 0.0161 for the slower ions. The plates also show a faint halo surrounding the disk and separated from it by about a quarter of the disk's diameter.

Fig. 1.

The pattern appears, at first sight, to resemble the diffraction of light by an opaque circular obstacle. However, a wave theory in which the atom and ion are treated as hard spheres gives a value of only 1 Å. for the collision radius and also predicts a wrong variation of disk radius with ion energy. The repulsive field model considered theoretically by Massey and Smith¹ gives a monotonic decrease of elastic scattering with increasing angle and therefore also fails to account for the effects.

A satisfactory explanation of the results has been found which seems definitely to establish the wave nature of lithium ions. The essential features of the theory are the inclusion of the attractive force due to polarization of the sodium atom, and the division of the ion wave-front into three distinct parts corresponding, respectively, to exceedingly small, large and intermediate scattering angles.

The first part is taken in such a way that the retardation produced by the potential field of the atom is everywhere less than half a wave-length. Under these conditions there is negligible refraction of the wave-front and only slight diffraction corresponding to a large circular obstacle (in atomic units). This gives a central Airy's disk of about 0.0006 in angular radius, which is considerably less than the angular radius of the incident beam. The second or innermost part of the wave-front is where the retardation varies very rapidly, corresponding to large angle scattering.

The remaining annular part of the wave-front is what produces the observed pattern. Now, the calculations show that the retardation varies almost linearly across the width of this region and a hollow cone of rays would therefore be produced, were it not for diffraction. This has the effect of filling up the inside of the cone and also producing fringes, spaced in accordance with the width of the annulus.

The fringes inside the cone are smoothed out by overlapping, thereby giving the observed uniform disk. The separation of the halo from the edge of the disk is related directly to the width of the annulus.

The calculations have been made for a force of the form²

$$F(r) = \frac{2\alpha s^2}{r^6} \left[1 - \left(\frac{r_0}{r} \right)^4 \right]$$

where α is the polarizability of the sodium atom and r_0 the equilibrium nuclear separation of Na Li⁺. For both 292- and 149-volt ions the observed radii of disk and halo agree, within the limits of the experiment, with those calculated for $\alpha = 2.5 \times 10^{-24}$ cm.³ and $r_0 = 2.36$ Å. Since only two observations are needed to fix both α and r_0 , this means that the theory correctly accounts for the observed variation of both radii with energy. The value of α fits in with the values found experimentally for Li, K and Cs by Scheffers and Stark³, and r_0 is consistent with the spectroscopic values⁴ of 2.67 and 3.07 for the neutral molecules Li₂ and Na₂. From the values of α and r_0 the binding energy of Na Li⁺ works out at 2.9 volts.

Fig. 1, *c*, shows the grazing-angle scattering of 292-volt lithium ions by a red-hot nickel target. As with sodium, there is a sharp intensity discontinuity, but the pattern has an approximately elliptical, and not circular, outer boundary.

A qualitative explanation of the effect is possible in terms of diffraction by single protruding surface atoms, using the same annular slit model as before, but with some allowance for the underlying atoms. The latter have the effect of smoothing out the potential behind the diffracting atom and consequently lessening the retardation gradient across the slit at that point. The pattern should accordingly be contracted in a direction normal to the target surface, as it actually is. It must be noticed that the retardation gradient across the slit bends the wave-front *towards the atom*, and therefore the part of the wave-front passing in front of the atom does not contribute to the pattern.

Vibration Temperature in relation to Rotation Temperature in Band Spectra

THE problem of exciting band spectra of two different molecules in the same source has attracted some attention of late. Investigation of excitation temperatures of molecules under these conditions has given interesting results which require elucidation from theory. For example, Lochte-Holtgreven¹ found by examining CH and C₂ bands in the same discharge tube a temperature difference of more than 1,000° between the two. On the other hand, van Wijk² arrived at a common effective temperature from the negative (N₂⁺) and second positive (N₂) bands of nitrogen in the same discharge tube. In view of these results, it was deemed necessary to undertake further work on the same lines.

The present investigation deals with AIO blue-green and CN violet systems excited in the same

arc and photographed simultaneously. The gross intensity measurements of all the bands in the two systems have been made by the methods of photographic spectral photometry by comparison with a standard source of known energy distribution. On the assumption of a Boltzmann distribution of vibrational energy in the initial state, temperatures have been calculated. These are shown below and compared with the results from the rotational energy distribution of previous authors for the same molecules examined in the carbon arc.

Band systems	Vibration temperatures (T. and T.)	Rotation temperatures (Ornstein and Brinkman)
CN, $B^2\Sigma \rightarrow \alpha^2\Sigma$	6300° K.	6500° K.
AlO, $^2\Sigma \rightarrow ^2\Sigma$	3460° K.	3275° K.*

* This is taken as the mean of two temperatures from 0,0 and 1,0 bands of AlO

It may be noted that the effective vibration temperatures of column 2 above agree fairly closely with the rotation temperatures of Ornstein and Brinkman. They are an indication of temperature equilibrium in the source (carbon arc) examined, as the values are supposed to be in the neighbourhood of the true temperatures for the zones concerned, for the CN bands are emitted from the inner violet part and AlO bands from the outer green halo.

The details of the investigation are being published elsewhere in a separate paper.

Intensity and Structure Changes of the $L\alpha$ Emission Lines of Cu and Fe on Intense Cooling of their Anticathodes

THE only previous experiments on the effects of temperature of the anticathode on the changes in the character of X-ray lines either in absorption or emission, are those of H. S. Read¹, J. H. Purks² and F. O. Chalklin³. These investigations, as also those of J. D. Hanawalt⁴, who studied changes in the fine structure of X-ray absorption spectra dependent on the physical and chemical nature of the absorber and temperature, were all concerned with the effects of high temperature alone. So far as we are aware, except for the experiment of Swedenborg and Claesson⁵, whose results were published while our experiments were in progress, there seems to be no record of any experimental investigations of the effect on the character of the X-ray lines emitted of intensely cooling an anticathode.

For effectively cooling the target, we had recourse to rapid evaporation of liquid oxygen from a specially designed anticathode tube. A plane grating spectrograph of the type devised by Siegbahn and Magnusson and constructed by Messrs. Adam Hilger, Ltd., was employed; while a molecular pump supplied by Leybold Nachfolger backed by a suitable oil pump was used for exhausting the apparatus. The grating used was ruled at Uppsala and had 900 lines in a space of 8 mm. Exposures were made first with liquid oxygen evaporating and then with tap

water circulating through the anticathode tube, on the same photographic plate. The time of exposure, bombarding electronic current (70 ma.) and the accelerating potential (4.8 kV.) were all kept constant during the two exposures. Although the grating used did not possess sufficient dispersion to resolve the L lines clearly, making quantitative measurements difficult, yet microphotometric studies of the photographs obtained have yielded the following interesting preliminary results:

(a) The line-curves of Cu and Fe L -lines possess considerable spread on the long-wave side but are steeper on the short-wave side at both the liquid oxygen temperature ($-188^\circ\text{C}.$) and room temperature ($25^\circ\text{C}.$) of the targets.

(b) The intensity of the Cu $L\alpha$ -line at the liquid oxygen temperature of the target is only 70 per cent of that from the target at room temperature. The corresponding figure for Fe is about 60 per cent.

(c) Although L -lines are not clearly resolved by the spectrograph used, which has a dispersion only of 4.95 Å. per mm., there is unmistakable evidence of their shift relatively to one another with the temperature change of the target.

(d) Some changes in the widths of the lines are also suggested with the change of temperature of the target.

The experiment is being repeated with a new plane grating possessing double the dispersion of the former, the experimental arrangements remaining more or less the same. It is hoped that it will be possible, on the conclusion of the experiments now in progress, to give definite quantitative results of measurements.

Surface Tension of Strong Electrolytes

Jones and Ray¹ have recently found that on adding a salt to water the surface tension at first decreases, then passes through a minimum and finally at concentrations above about 0.001 N increases with increase of concentration. The interionic attraction theory of surface tension developed by Wagner² and Onsager³ on the basis of the Debye solution theory and the principles of electrostatics requires, however, the slope of the surface tension-concentration curve always to be positive and greater at the lower concentrations. The accurate results of Jones and Ray are thus seen to be in complete disagreement with theory.

By postulating that the surface structure of water is such that there is a small number of surface locations where negative ions can become adsorbed from the interior of the solution with a large diminution of potential energy, it is possible to derive statistically the following equation for the number of moles of an ion kind adsorbed per sq. cm.

$$\Gamma_i = -ck_i \left[\frac{a - \{b - ck \sum v_i\} e^{-W/RT} - ck_i v_i}{(b - ck \sum v_i) e^{-W/RT} + ck_i v_i} \right] \quad (1)$$

which when coupled with the Gibbs adsorption isotherm yields (neglecting activity coefficients)

$$\gamma - \gamma_0 = RTkc \Sigma v_i + \frac{aRT \Sigma v_i}{\sigma W_- / RT \Sigma v_i - v_-} \ln \left[1 - \frac{(\sigma W_- / RT \Sigma v_i - v_-)kc}{\sigma W_- / RT} \right] \quad (2)$$

The term $\sigma W_- / RT \Sigma v_i$ can be shown to be very much smaller than v_- , with the result that (2) reduces to

$$\gamma - \gamma_0 = RTkc \Sigma v_i - \frac{aRT \Sigma v_i}{v_-} \ln \left[1 + \frac{kv - \sigma}{\sigma W_- / RT} \right] \quad (3)$$

where γ is the surface tension at concentration c (moles per litre), a is the number of adsorbing points per sq. cm., b is the number of water molecules per sq. cm., W_- is the potential energy of the negative ion at the surface in excess of its value in the interior of the liquid, and k is the ratio between the concentration in moles per sq. cm. and moles per litre, and depends on the thickness of the adsorbed layer, which we take as the diameter of the water molecule plus that of the adsorbed solute.

Knowing the diameters of the water molecule and of the solute ions, and estimating a and W_- from the data of Jones and Ray, it is possible to calculate the surface tension from (3) for potassium chloride solutions, for example (lower solid line of Fig. 1), and to compare with the experimental results (crosses of Fig. 1). The agreement is satisfactory.

Fig. 1.

In the case of capillary inactive non-electrolytes like sucrose, a will be equal to zero and (3) becomes

$$\gamma - \gamma_0 = RTkc. \quad (4)$$

From the density of solid sucrose one can calculate an approximate value of its molecular diameter allowing an evaluation of k to be made and a computation of the surface tension from (4). The upper solid line of Fig. 1 represents the theoretical calculations, while the circles are the experimental data of Jones and Ray. Again the agreement seems to be satisfactory, and lends support to the original postulate.

Viscosity of Monomolecular Films

ALTHOUGH the viscosity relations of films are of fundamental importance for an understanding of their structure, it has not in the past been possible, with the surface viscosimeters used, to determine the viscosity of a true film, that is of a monolayer. Two viscosimeters which are sufficiently sensitive are described below, and others are in process of development.

1. *Capillary slit viscosimeter for liquid surface films.* The film is allowed to flow under its own pressure, or a difference of pressure, through a long transverse slit in a barrier which confines the film. The following relation gives the viscosity (η):

$$\eta = \frac{f}{Q} \frac{d^3}{12l} \text{ dyne sec. cm.}^{-1},$$

where f is the surface pressure in dynes per cm., d is the diameter; and l the length of the slit, and Q is the number of sq. cm. of film which disappears through the slit per second.

VISCOSITY OF SURFACE FILMS OF FATTY ACIDS IN SURFACE PORES

No. of C Atoms	Saturated Acids at 25°C.
14	Myristic 0.000161
15	Pentadecylic 0.000228
16	Palmitic 0.000248
17	Margaric 0.000317
18	Stearic 0.000307
19	Nonadecanoic plastic solid
20	Arachidic 0.001790
18	Unsaturated Acid at 20°C. 0.000162
	Oleic

2. Torsion ring surface viscosimeter for liquid and plastic-solid films.

A torsion pendulum, with a horizontal circular disk at the bottom, was constructed. This disk may be allowed to vibrate in the surface, but is insensitive to the film. A thin metal cylinder, 1 cm. high, was soldered to the outside of the ring in such a way that only the sharp lower edge of this cylinder could be put in contact with the surface of the water. By allowing this ring (10 cm. in diameter) to vibrate in contact with the clean surface, and then with a film outside, but not inside the ring, the viscosity of the film could be calculated from the logarithmic decrements of angle between successive swings.

This instrument gave data of great interest. For example, cetyl alcohol on 0.01 molar hydrochloric acid at 22°C. compresses at very low pressure to a liquid monolayer of 21 sq. A. area per molecule. As the pressure is increased, the viscosity of the liquid film increases, as is shown by both types of viscosimeter. The force-area relation is linear to 11 dynes and 19 sq. A., and at this kink point a change of phase occurs, in which a plastic solid film of very much higher viscosity and lower compressibility appears. The viscosity of this film increases rapidly with pressure. Pentadecylic acid, which forms an expanded film the pressure of which begins to increase above 0.1 dyne per cm. at 44 sq. A., forms a liquid film both below and above the kink, and the solid plastic form appears where no kink is visible at a molecular area of 21 sq. A.

The viscosity of monolayers is found to be highly dependent upon the tightness of packing of the molecules in the film, and, as the table indicates, it increases rapidly with the length of the molecule in condensed films which exhibit an orientation of the molecules perpendicular to the surface.

ROBERT J. MYERS.

Spectroscopic Observations of Reactions between Lactoflavin, the Coulter Compound, 'Cytochrome b', and Cytochrome c

FROM diphtheria toxin, one of us (M. D. E.) has prepared a solution containing the "complex porphyrin" of Coulter¹, and also a compound characterized by an α -band located in the same position as that of cytochrome b (563 m μ). The preparation will be described elsewhere.

When oxidized lactoflavin was added to this solution, at 30° C. and pH 7.4, the 574 m μ and 563 m μ bands disappeared instantly. When lactoflavin was reduced by hydrosulphite, the 574 m μ and 563 m μ bands reappeared at once. The 574 m μ and 563 m μ compounds must therefore be in the reduced state.

Reduced cytochrome c was added next to this solution. A paradoxical phenomenon was observed: the 574 m μ and 563 m μ bands again disappeared, as if reduced cytochrome c had oxidized the reduced 574 m μ and 563 m μ substances. Cytochrome c was obtained from a stock solution by acetone precipitation; the stock solution had been prepared in Prof. Keilin's laboratory by Dr. F. Stare.

In a separate experiment, oxidized cytochrome c was added to the solution of 574 m μ and 563 m μ substances. All the bands remained unchanged, indicating that no reaction had occurred.

Lactoflavin is not necessary for the reaction between reduced cytochrome c and the reduced 574 m μ and 563 m μ substances. This was shown by adding reduced cytochrome c to the 574 m μ and 563 m μ compounds. The 574 m μ and 563 m μ bands disappeared. This reaction can be partly reversed by the immediate addition of a few drops of 5 per cent potassium ferriyanide solution. Oxidized cytochrome c appears, and the 574 m μ and 563 m μ bands re-appear in diminished strength. The 574 m μ and 563 m μ substances alone do not react with ferriyanide. A solution containing the 574 m μ compound alone reacted exactly like the mixture of the 574 m μ and 563 m μ compounds.

The following hypothesis summarizes the observations and interprets the paradox: when the iron atom of cytochrome c is in the divalent state, the 574 m μ and 563 m μ compounds can be oxidized by the porphyrin ring of cytochrome c; but when the iron is in the trivalent state, the porphyrin ring cannot oxidize the 574 m μ and 563 m μ substances.

These reactions between cellular catalysts are interesting in themselves. In addition, a more exhaustive investigation will bring out whether or not they are related to the Pasteur reaction.

Oxidation of Cholesterol and Dehydroandrosterone by Means of Osmic Acid

UNSATURATED compounds are known to add, under the action of osmic acid, two hydroxyl groups at the place of their double bond¹, these groups being in *cis*-position with regard to each other. The reaction course is analogous to that produced by KMnO_4 . However, action of the latter on cholesterol¹ yields but 4-5 per cent of *cis*-cholestan-triol. Thus KMnO_4 is unsuitable for the oxidation of the double bond in

sterol-derived hormones, in particular in dehydroandrosterone.

After we had obtained *trans*-androstan-(17)-one-(3,5,6)-triol from dehydroandrosterone oxide² we desired to obtain also the *cis*-compound for the sake of comparing their physiological activities. The method has been worked out for cholesterol⁴, then transferred to dehydroandrosterone.

Equivalent amounts of anhydrous cholesterol and osmic acid, dissolved in water-free ether, are allowed to react for 2-3 days. The ether is then distilled off and the black residue boiled with an aqueous-alcoholic solution of Na_2SO_3 for two hours. When working with cholesterol only traces of the looked-for product—cholestan-triol—are found in the water-alcohol filtrate; most of it is obtained by extracting the black residue with boiling alcohol. The *cis*-cholestan-triol obtained melted, after washing with ether, at 238.5-239.5°. Mixed with the *trans*-compound it caused depression of the melting point.

On oxidizing dehydroandrosterone with OsO_4 , almost the whole of the androstanone-triol passes into the aqueous-alcoholic solution (after boiling with sulphite). Yield of the crude product: 70 per cent. Recrystallized from ethyl-acetate; transparent rectangular prisms, m.p. 243.5-244° (corr.; sinters at 242.5°). Analytical data agree with the formula $\text{C}_{19}\text{H}_{28}\text{O}_4$.

We intend applying the same method also to androstene-diol, androstene-dione and testosterone.

The present work is to be published shortly in detail.

⁴ Orlegue (loc. cit.) mentions having obtained some *cis*-diols of the sterol group; he does not give any details, nor mention what sterols he worked with.

Decomposition of Benzene-Diazonium Chloride

To test the suggestion¹ that the decomposition of aromatic diazo compounds might be non-ionic in mechanism, I have been investigating the decomposition of benzene-diazonium chloride in the presence of non-aqueous solvents. When suspended in an organic liquid, benzene, diazonium chloride appears to melt at about 50° C. and then immediately a violent decomposition sets in. There is great heat evolution, and, except on the small scale, the reaction tends to become explosively violent. Often hydrogen chloride is evolved, and whenever its formation has been observed, chlorobenzene has been found amongst the reaction products.

From an examination of the decomposition in acetone, it appears possible that the chlorobenzene is produced by a secondary reaction between the decomposing benzene-diazonium chloride and the hydrogen chloride, since when an excess of chalk is added to keep the mixture neutral, the principal reaction that occurs is

for both benzene and chloroacetone were isolated in good yield.

Since chloride anions do not attack acetone, it follows that the decomposition of benzene-diazonium chloride, $(\text{Ph.N}_2) + \text{Cl}^-$, is not a direct decomposition of a diazonium cation, nor yet an intramolecular process. The mechanism:

diazonium salt covalent diazo-compound free neutral radicals

will accord with facts. When this decomposition in acetone, kept neutral with chalk, is carried out in the presence of the relatively inert metals antimony, bismuth, lead and mercury, a rapid reaction occurs at room temperature and the metal is attacked. With mercury, phenyl-mercuric chloride is produced.

These reactions with metals are undoubtedly similar to those which I have previously observed during the decomposition of benzene diazo-acetate¹, and are closely paralleled by the observations of Neamejanov and his colleagues², who have obtained organometallic compounds by decomposing certain diazonium double salts with metals such as copper, tin and zinc.

To substantiate the experimental evidence reported above, the work is being extended to reaction in other organic liquids.

Structure of β -Boswellinic Acid

THE investigations of Ruzicka, and of Winterstein and their co-workers, have shown that the majority of the triterpene acids (hederagenin, gypeogenin, oleanolic acid, sial- and suma-resinolic acids) are in all probability θ -hydroxy- γ : δ -unsaturated mono-basis acids, as indicated in the accompanying formula¹. On

the other hand, β -boswellinic acid, $\text{C}_{30}\text{H}_{48}(\text{OH})\text{COOH}$, one of the principal triterpene constituents of frankincense, evidently possesses a somewhat different constitution, for on mild oxidation with chromic anhydride this acid is converted into a monoketone $\text{C}_{30}\text{H}_{46}\text{O}$, m.p. 196° (found: C, 84.53; H, 11.11. $\text{C}_{30}\text{H}_{46}\text{O}$ requires C, 84.80; H, 11.30 per cent), which has been characterized by the preparation of an oxime. Oxidation under similar conditions of β -boswellinic methyl ester, however, furnishes the corresponding keto-ester, m.p. 160° (found: C, 79.12; H, 10.20. $\text{C}_{29}\text{H}_{44}\text{O}_2$ requires C, 79.41; H, 10.33 per cent), which forms an oxime, m.p. 200° .

These findings necessitate the assumption that β -boswellinic acid is a β -hydroxy-acid, the expected

facile elimination of carbon dioxide from the β -keto-acid first formed during the oxidation giving rise to the ketone $\text{C}_{30}\text{H}_{46}\text{O}$. The requisite grouping

$-\text{CH}(\text{OH})\cdot\text{C}\cdot\text{COOH}$ may be derived from structure I by putting $\text{R} = -\text{COOH}$.

It is of interest to note that in gypeogenin $\text{R} = -\text{CHO}$, and in hederagenin $\text{R} = -\text{CH}_2\text{OH}$, and it is significant that oxidation of the primary alcoholic group of the latter compound gives a β -hydroxy-acid, the further oxidation of which is exactly analogous to that of β -boswellinic acid².

A full account of this investigation will be published elsewhere.

Succession of Broods in *Lebistes*

IN connexion with the note by G. L. Purser in NATURE of July 24 on "Succession of Broods of *Lebistes*", it has long been known that several of the viviparous fish, such as *Lebistes*, are fertilized for a long time after one copulation. E. Philippi has described this phenomenon in *Glaridichthys*¹. Johs. Schmidt found it in *Lebistes*². He says that he had observed seven broods in succession. I have noted up to eight broods³.

In my paper in 1922 I gave a photomicrograph showing the spermatozoa lying ready in the ovary for the next fertilization, with their heads as near the immature eggs as possible. Plainly enough there is competition between the spermatozoa, and it is remarkable that when a female has been fertilized by a male of one race of *Lebistes* and has produced some few broods within a few months, and then a new male of another race of *Lebistes* is put into the tank immediately after a birth, the next brood will be from fertilization by the new male. The old spermatozoa cannot compete with the fresh ones. Ordinarily a mixed brood is only obtainable when both males are together with the female at the same time.

Homologous Loci in Wild and Cultivated American Cottons

ON cytological grounds¹, the New World cultivated cottons are thought to be allopolyploids with two genomes each of thirteen chromosomes derived from species cytologically homologous with the present Asiatic *arborum-hortacorum* group of species and with the North American thirteen chromosome species (*aridum*, *Armourianum* and *trilobum*). Genetical confirmation of the part played by the present cultivated Asiatic cottons or their ancestors in the origin

of the New World cultivated group, was later provided by my demonstration² that a gene could be transferred from an Asiatic to a New World cotton by repeated back-crossing.

Genetical confirmation is now available regarding the existence in the thirteen-chromosome North American species of genes which have alleles in the cultivated cottons with $n=26$ chromosomes. Hybrids between *G. barbadense* L. (Sea Island) and the wild species *G. aridum*, *G. Armourianum* and *G. trilobum* were found to be weakly fertile on the male side. After making two successive back-crosses of the hybrids with *barbadense* or *hirsutum*, fertility was completely restored, and the following transferences of genes from the wild to the cultivated species were effected:

1. Normal (σ^r) from *aridum* to *barbadense* (σ^r).
2. Normal (σ^r) from *Armourianum* to *barbadense* (σ^r).
3. Normal (σ^r) from *trilobum* to *barbadense* (σ^r).
4. (S^B) Petal Spot from *aridum* to *barbadense* and *hirsutum*.
5. (SAB) Petal Spot from *Armourianum* to *barbadense*.

The slight impairment of dominance of the crinkled heterozygotes of *aridum* and *trilobum* which persists in the second back-cross of *barbadense* crinkled,

suggests that the normal alleles of these species may not be identical with the *barbadense* normal allele, but may differ in dominance potency. If they prove to differ in this way, they will resemble the weaker normal alleles at this locus established to be present in upland cotton (*G. hirsutum* L.).

The genes for petal spot of *aridum* and *Armourianum* respectively appear to be different from the petal spot genes of either *barbadense* or *hirsutum*, but their relationship with the spot genes of these species has not yet been elucidated.

To sum up: it is now established on genetical as well as cytological grounds that the New World cultivated cottons are amphidiploid in origin and that thirteen-chromosome species from both Asia and North America have played a part in their formation. My previous hypothesis³ that the New World group originated in late Cretaceous or early Tertiary time in a former Polynesian land mass also receives further support.

Points from Foregoing Letters

Dr. G. W. Brindley and P. Ridley discuss the two kinds of asymmetry found in certain metals having a hexagonal structure—symmetry of the lattice vibrations and asymmetry of the atoms. It is pointed out that in ruthenium the atomic asymmetry is of a different type from that found in zinc and cadmium.

A new equilibrium diagram for the system iron-carbon has been prepared by Dr. I. Iitaka. The author claims that it eliminates the difficulties of the 'single' diagram by assuming Fe_3C to decompose on solidifying or on separating from austenite, and overcomes those of the 'double' diagram by omitting super-cooling.

Photographs showing the scattering of lithium ions by sodium vapour and by a red-hot nickel target (at grazing angle) are submitted by A. G. Emalie, who also supplies an explanation which, he considers, establishes the wave nature of the lithium ions.

By photographing AIO blue-green and CN violet bands simultaneously in the same arc, gross intensities of both have been measured by Dr. N. R. Tawde and S. A. Trivedi by the methods of photographic spectral photometry. Vibration temperatures have been calculated and compared with the available rotation temperature data on these molecules.

Intense cooling of copper and of iron anticathodes changes the character of the X-rays which they emit. Prof. K. Prosad and A. T. Maitra find that the intensity of the copper L_{α} line is decreased at liquid oxygen temperature. The L -lines shift relatively to one another, and there are indications of changes in width.

Prof. M. Dole suggests a formula for calculating the surface tension of strong electrolytes which gives calculated values in satisfactory agreement with those found experimentally for potassium chloride solutions, including the observed decrease in surface tension at low concentrations. The formula is obtained by postulating a small number of surface

locations where negative ions can be adsorbed from the interior of the solution with a large diminution of potential energy.

Two methods for measuring the viscosity of monomolecular films are described by Prof. W. D. Harkins and R. J. Myers: one, in which the film flows through a transverse slit in a barrier confining the film, and another method depending on the vibration of a ring the inner circumference of which is in contact with a pure surface while the outer is in contact with the film. A table giving viscosities of fatty acid films shows that the viscosity increases rapidly with the length of the molecule.

Prof. F. Urban and Dr. M. D. Eaton describe several reactions between laetoflavin, cytochrome *c* and the "complex porphyrin" of Coulter (prepared from diphtheria toxin). The authors infer that the porphyrin ring of cytochrome *c* can oxidize the compounds in Coulter's complex (which are responsible for the absorption bands at 574 m μ and 583 m μ) only when the iron atom of cytochrome *c* is in the divalent (reduced) state, and not when it is in the trivalent state.

The oxidation of the male sex hormone, dehydroandrosterone, by osmic acid to produce the α is form of androstanone-triol, by addition of two hydroxyl groups, is described by Prof. M. Ushakov and A. Lutenberg.

Dr. W. A. Waters finds that when benzene-diazonium chloride decomposes in acetone in presence of chalk, benzene and chloroacetone are formed, and if metals such as lead, antimony or mercury are present, these are attacked. The reactions are explained by supposing that free neutral radicals are liberated as the diazo compound decomposes.

From the products of oxidation of β -boswellinic acid (one of the principal constituents of frankincense) Dr. J. C. E. Simpson concludes that the compound is a β -hydroxy-acid.

Research Items

Antiquity of Man in Rhodesia

WITH the view of determining the disputed question of the age of the stone implements of the Zambesi gravels, first described in 1905, the Rhodesian Archaeological Expedition of 1929 undertook to investigate the antiquity of man in Rhodesia as demonstrated by the implements occurring in the gravels south of the Falls, their cultural sequence and the relation, if any, of the gravels and their contents to the stages in the recession of the Falls and the excavation of the Zambesi gorge. The results of the archaeological investigation have now been reported by Mr. A. Leslie Armstrong and the Rev. Neville Jones, while the necessary geological preliminary considerations are embodied in notes on the geology of the area by H. B. Maufe, director of the Geological Survey of Southern Rhodesia (*J. Roy. Anthropol. Inst.*, 66, 2). The conclusions are summarized as follows: Over the area examined south of the Falls, the Zambesi formerly flowed over the site of the existing gorge at a level comparable with that of the river to-day north of the Falls, and more than 400 ft. above its present level. The terrace gravel and the old river-bed gravel are true residual Zambesi gravels, deposited when the river flowed over the site of the present gorge. The contained implements of Lower and Middle Palaeolithic type are at least as old as the gravels in which they occur. The implements belong to a definite sequence of seven cultural groups from Pre-Challeian to Bambata (Aurignacian). With the exceptions of groups (1) and (7) the cultures represented are South African equivalents of the recognized European series, occurring in the same order of succession, at least as ancient in time, and showing close parallels in type and technique thereto. The Pre-Challeian implements are the earliest recognizable traces of man's occupation of the valley, and antedate the erosion of Gorge 5, the Falls then being to the south. The successive stages in the recession of the Falls and erosion of the Gorge since Pre-Challeian times can be related to the successive stages of culture. Since Pre-Challeian times, two arid and two pluvial periods have supervened. Man in Rhodesia is of an immense antiquity, at least equal to man in Europe.

Colour Changes in Elasmobranch Fishes

THE question of the control of the colour changes that occur in the elasmobranch fishes is a vexed one, and indeed the method may not be the same in different members of the group. Light has been thrown on the subject by G. H. Parker (*Proc. Amer. Phil. Soc.*, March 1937). The animals were anaesthetized by immersion in very cold water, a method that has advantages over anaesthetizing by drugs. The dark phase is induced by a neurohumour produced by the posterior lobe of the pituitary gland. The pale phase in *Raja erinacea* is due to the absence of a dispersing factor and in *Mustelus canis* and *Squalus acanthias* in part to nervous action. The concentrating neurohumour in the last two species is in the nature of a lipohumour soluble in olive oil but not in water, and a stable substance possibly a sterol.

Feeding Mechanism of *Apsoudes*

THE Crustacean *Apsoudes* is of special interest to the morphologist since it links the Isopoda with the primitive Mysidacea, which are presumed to form the starting point of the Peracaridan series. Very little, however, is known of its habits and mode of life. This deficiency is in part supplied by R. Dennell in a finely illustrated memoir (*Trans. Roy. Soc. Edin.*, 59, Pt. 1, No. 2, 1937) in which the method of feeding is discussed in relation to the evolution of the feeding mechanisms in the Peracarida. The exact relations of mouth-parts, carapace and associated structures are described in greater detail than has hitherto been done, and the mode of action partly described from observations on the living animal and partly inferred from a study of anatomical relations. It is concluded that the essential features of the primitive Peracaridan filter-feeding mechanisms are represented, but that this method of obtaining food is of little importance and is in process of replacement by raptatory feeding, which is the method followed by most Isopoda. Modifications in the carapace and particularly in the organs concerned in maintaining the respiratory current are adaptations to life in a muddy habitat.

Egg-Killing Washes

It has been shown that the ovidical properties of tar oils to *Oheimatobia brumata* L., *Lygus pabulinus* L., *Plesiocoris rugicollis* Fall. and *Psylla mali* Schm. increase with increase in boiling range. Petroleum oils, however, although their general insecticidal properties are known to increase with boiling range, fail to inhibit the hatching of aphid and psyllid eggs, which has led to the suggestion that ovidical action to such eggs is associated with a chemical toxicity possessed by tar oils but not, in general, by petroleum oils. Moreover, some diversity of evidence exists regarding the relative toxicity of high- and low-boiling tar oils to *Aphis pomi* De Geer. Kearns, Martin and Wilkins (*J. Pom. and Hort. Sci.*, 15, 1, 56; 1937) have investigated this discordance in an examination of the comparative ovidical efficiencies of high- and low-boiling oils, the validity of solubility in dimethyl sulphate as a criterion of toxicity and the importance of chemical composition. A wide range of tar and petroleum oils was tested and parallel chemical analyses carried out together with determinations of boiling ranges and solubilities in dimethyl sulphate. Ovidical efficiency showed no relation to the total content of hydrocarbon oil in the emulsions, but was highly correlated with the content of neutral oils soluble in dimethyl sulphate. The toxicity of oil from which certain oxygenated derivatives were removed by fractionation with hydroferriehloric acid was not significantly different from untreated oil, and an examination of a number of individual compounds for possible toxic properties gave no indication of any specificity of this kind. In the absence of any large differences in the ovidical properties of high-boiling neutral oils soluble in dimethyl sulphate derived from various sources, the solubility test is regarded as an adequate practical method of assessing the toxicity of hydrocarbon oils to *A. pomi*.

Run-off after Rainstorms

A PAPER by Mr. J. R. Daymond, an abstract of which is published in the *Journal of the Institution of Civil Engineers* (No. 7, 1936-37; June 1937), discusses the estimation of run-off from areas subjected to rainstorms in connexion with a law first proposed by Mr. Emil Kuichling in a paper contributed to the American Society of Civil Engineers (*Trans. Amer. Soc. Civ. Eng.*, 20; 1889) that "... in drainage areas of moderate size the heaviest discharge always occurs when the rain lasts long enough at its maximum intensity to enable all portions of the area to contribute to the flow. For large areas, on the other hand, a more elaborate analysis becomes necessary in order to find under what conditions the absolute maximum discharge will occur, ..." As the law is often misquoted to the extent of ignoring the proviso and is thus misinterpreted, the object of Mr. Daymond's paper is to show that the reservation regarding large area is valid and important. In addition, an important general conclusion is arrived at, applicable to all areas, namely, that provided the rain falls at a constant intensity, the storm that gives the maximum run-off is one which lasts for a time less than, or equal to, the time of flow from the farthest point of the drainage area to the point of outfall from the area.

Precursors of a Volcanic Eruption

THE tilting of the flanks of the volcano Asama (Japan) in 1936 is described by R. Takahasi and T. Minakami in a recent *Bulletin of the Earthquake Research Institute* (15, 463-491; 1937), while the changes in depth of the crater in 1934-36 are recorded by Minakami (*ibid.*, 15, 492-496; 1937). Tiltmeters were erected at three stations, 4 km. east, 5 km. north, and 12 km. south-west of the crater. In 1936, explosions were frequent in February-March and July-August, and, during intervals of 7-30 days before then, marked changes of tilt were recorded almost simultaneously at the three stations, the variations being about five times as large as those observed during intervals of quiescence and being clearly independent of changes in air temperature. The tilts were accompanied by remarkable uplifts of the crater floor as a whole. The depths of several points on the floor were determined by triangulation from stations on the crater rim. After a pause of inactivity in July-October 1934, the floor began to rise, the uplift being about 70 m. by the time of the violent explosions on April 20, 1935.

Surface Layers on Glass and Silica

LORD RAYLEIGH (*Proc. Roy. Soc., A.*, 160, 514) observed that there was always some reflection from the boundary when polished glass surfaces were put in optical contact. Further investigations were made by immersing plates of glass or silica in a liquid adjusted to have the same refractive index as the bulk material. The reflection from fire-polished surfaces was found to be very low, but the reflection from surfaces which had been polished was quite appreciable, indicating the existence of a surface film of refractive index different from the bulk material. The refractive index of the film could be determined by finding a liquid mixture which gave minimum reflection. The index rises with the violence of the polishing treatment. In the case of fused quartz ($\mu = 1.46$) the index of the surface film could be brought up to 1.6 by polishing. The modified

surface film could be removed by hydrofluoric acid. It appears to be in fact a modified form of silica, probably with a depth of about 300 Å. Similar but much less marked effects were observed with glasses, and a very small effect with crystalline quartz. Crystalline quartz surfaces can therefore be optically contacted without much reflection at the interface, due to the akin effect. It is shown that most of the reflection observed in this case is due to the distance between the contacted surfaces, which is found to be about seven times the crystal spacing of the silicon atoms.

Built-up Molecular Films

K. B. BLODGETT and I. LANGMUIR (*Phys. Rev.*, 51, 964) have been able to build up films of various stearates on glass or metal surfaces by dipping the plates through a monomolecular layer of stearic acid spread on water containing salts of barium or other metals. The monolayer is kept under two-dimensional pressure. The first layer attaches itself to the surface by its carboxyl groups as the plate is raised from the water, the second layer attaches with its molecules reversed when the plate is dipped again, and so on. The layer is thus folded back on itself at each dipping. The presence of a little copper facilitates the production of thick films, and films containing 3000 layers have been built. The films are uniaxial crystals with the optic axis perpendicular to the surface. The optical properties of the film have been studied and the ordinary and extraordinary refractive indexes are 1.491 and 1.551 respectively. If a film which has been built up on a barium solution at pH 8.5 is treated with benzene, stearic acid is dissolved out and the resulting skeleton film has a nearly unaltered thickness but a much lower refractive index.

Double Stars and Relativity

IN a paper delivered at the Tercentenary Conference of Arts and Sciences at Harvard on September 4, 1936, Prof. T. Levi-Civita shows that the relativistic equations of motion of two bodies of comparable size can be integrated by treating relativistic effects as perturbations (*Amer. J. Math.*, 59, 225; 1937). Two results are obtained, which, it is hoped, may be tested by observation of double stars. The first gives a formula for the angular precession of the periastron of the satellite star. The second is more striking. It predicts that the acceleration of the centre of mass of a double star lies entirely in the plane of the relative orbit. This acceleration may be divided into a fluctuating periodic part, and the secular part, the effects of which accumulate during the successive revolutions. The secular acceleration of the centre of mass is directed along the major axis towards the periastron of the principal star. A formula is obtained for the increase of the velocity of the centre of mass during a century, which ought to be detectable eventually by spectroscopic observation. Prof. Levi-Civita has also considered the general case of n bodies (*ibid.*, 59, 9; 1937), but in this case no definite results capable of observational test have been reached. In a discussion on this paper at Princeton (October 7, 1936), Prof. A. Einstein suggested that an extra term, corresponding to the stresses keeping a body together, was needed in the equations. Prof. Levi-Civita adopted this suggestion, but found that it did not affect the conclusions previously reached.

International Population Congress in Paris

A VERY successful Congress to discuss population problems was held in Paris on July 29–August 1 last, under the presidency of M. Adolphe Landry. The Congress was honoured by the patronage of M. Albert Lebrun, President of the Republic, who attended the opening session. Before this, on July 28, a meeting of the General Assembly of the International Population Union took place; and it may be noted that the Congress was held under the auspices of the Union, which took a definite part in the arrangements for the Congress. At the General Assembly, M. Adolphe Landry was elected president of the Union in succession to Sir Charles Close. M. Landry is a former Minister of State, whose interest in demographic matters is well known. He has written several works on the subject, particularly "La Révolution Démographique" (1934). His management of the Congress was most happy.

During the four working days of the Congress, about 170 papers were presented for reading and discussion. Abstracts of the papers were available at the opening of the Congress, but, as always happens at international meetings of this kind, individual delegates must select their lectures and must necessarily miss some contributions of importance. Some of the papers, particularly the mathematical ones, were difficult to follow at the time, but will be available for study when the proceedings are published. Perhaps the real value of these congresses consists largely in the personal contacts established between workers of different nationalities, who cease to be abstractions to each other and can use the occasion for informal discussions and exchange of views.

The Congress was divided into five sections which were simple and sufficiently comprehensive to cover the whole field. A few of the titles of the lectures will serve to give an idea of the kind of questions which were discussed, thus: "The Calculation of Death-Rates"; "Sur les possibilités de retour à l'équilibre pour une population régressive ou rétrograde"; "A Population Growth-Curve for England and Wales"; "Essai d'établissement d'un indice de densité économique de population"; "Considérations sur la politique démographique d'Auguste et ses effets"; "The Length of Life in the Early Roman Empire"; "Recent Population Movements in the Irish Free State"; "Les types de migrations"; "Die natürliche Bevölkerungsvermehrung Wiens"; "L'évolution sociale de la population italienne à travers les recensements"; "Growth of Urban Population in the United States"; "Fécondité et classe sociale en Suède"; "L'influence du chômage sur la famille"; "Die neue deutsche Bevölkerungsentwicklung"; "Rural Population and Government Policies in the United States"; "Biotypes et fécondité"; "Constitution physique de la jeunesse polonaise".

Now, this is a very mixed bag; but the various aspects of the subject are inter-linked and affect one another. It would be a mistake, for example, to discuss only the statistical side of the population question and to omit consideration of quality. In the same way, an adequate examination of present-day tendencies necessarily involves a study of what has happened in the past; and a discussion of demographic facts in one country is imperfect without reference to what is happening elsewhere.

In view of the considerable range of matter discussed and of the impossibility of being present at more than one section at a time, one can only get a limited, personal impression of the meeting, an impression to be corrected by a study of the proceedings when these are eventually published. Meanwhile, no one can have attended this Congress without having learnt something more about the intricacies of the subject than he knew on arrival. Such papers as that of Prof. Burgdörfer, for example, which dealt chiefly with the effect on the birth-rate of Germany of the new population policy in that country, have an importance for all of us. The abstract of his paper ends with the following sentence: "L'exemple de l'Allemagne prouve que, dans notre civilisation occidentale, il est possible de lutter avec succès contre la baisse du taux de natalité".

Amongst numerous other important contributions to the proceedings may be mentioned the paper by Prof. A. M. Carr-Saunders and Mr. R. S. Walshaw, on "Recent Population Movements in Ireland". The authors remark that, "There is less emigration [from Ireland] than formerly, and it is going to the United Kingdom instead of to the United States. This raises important problems for the United Kingdom, which is faced with the prospect of a declining population. The United Kingdom is still pursuing a policy of giving financial assistance to emigrants going to the Dominions. It is doubtful if this can be continued, and it is a question whether the United Kingdom will not be peopled from Ireland".

RACE AND RACIAL DOCTRINE

ONE section of the International Congress was devoted to matters coming under such heads as biometry, biotypology and heredity. Opportunity was thus afforded for the discussion of a variety of problems connected with the racial question, of which advantage was taken by the Management Committee of the Groupement d'Etude et d'Information "Races et Racisme", an organization which has undertaken the dissemination among the French people of information relating to the fallacies and consequences of the racial doctrines now current in Germany, and is responsible for the publication of the periodical *Races et Racisme* (see p. 458). Arrangements were made for presentation to the Congress of a number of communications dealing with questions bearing upon "race" and their formal discussion. The following account is based upon a report furnished by the organization.

Among those present were the veteran Prof. Franz Boas, who notwithstanding his advanced years had crossed the Atlantic from America for the special purpose of taking part, and Prof. Lips and Prof. Fairchild, also from the United States. A certain 'liveliness' developed in the proceedings owing to the presence of numerous representatives of Germany, among whom were Prof. Rüdin, director of the Kaiser Wilhelm Institute, Prof. Verschuer of the University of Frankfurt, and Prof. Hellpech of Heidelberg.

In opposition to views put forward by German delegates on 'purity' of race and 'nordization', Prof. Boas, basing his remarks on the experience of half

a century, contended that a definition of race more in accord with realities was an urgent necessity. In even the most inbred populations there were family lines of descent which included different genetic characters, while in every family line were frequently included individuals of most diverse genetic types. There was, he maintained, no population which from the racial point of view was so uniform as to be considered either anatomically or physiologically a unity. The different groups of the white races so far resemble one another that often extremes of the same type are more diverse than the means of two different types. He stressed the influence of environment, and showed how, in the United States, attitude and gesture, which have been said to be determined by race, were modified in the American-born descendants of immigrants.

Prof. J. Brutzkus dealt with the racial bearing of his research on the blood groups of Jews, which he said pointed to a differentiation of four types: Semitic, Western European, Mixed Eastern European and Mongoloid. Further, this differentiation corresponds with the differentiation of head-form. The diversity of Jewish types is due on one side to the crossing of the Semitic type with the proselytes of the Roman Empire, and on the other with those of the Khazar. He maintained that according to the evidence of the blood group the Jews of Berlin are more purely European than the Germans themselves, while the Jews of the Crimea and the Caucasus are more purely Asiatic than the autochthonous Tartars.

The fundamental principle of racial doctrines was attacked by Dr. Zolleshan of Prague, who maintained that recent research among the most remote peoples in Europe and the most primitive in other parts of the world had shown that the doctrine of the persistence and immutability of racial type was untenable. The claim to a superiority of racial type was based on the desire to dominate. In conclusion, he suggested a world-wide collaboration of scientific institutions, concentrating on the investigation of the problems of race.

This proposal was strongly condemned by Prof. J. Thurnwald of Berlin, who maintained that no man of science was capable of considering any scientific problem whatsoever without importing into his conclusions elements which were the immutable outcome of his race.

Considerable discussion was also aroused by a communication from Dr. Ritter on the racial composition of the gipsies of Central Europe, in which it was shown that their mixed racial character justified the measures of 'purification' which had been taken by the Third Reich. This contention was opposed by Dr. Brutzkus, who maintained that the "Bohemians" were the most authentic and the purest descendants of the Aryan race.

Debate became particularly lively in discussion of the report on "The Eugenics of Mental Disease", presented by Prof. Rüdin, in which the necessity was urged for the sterilization of all persons known to be affected by hereditary disease. Prof. Schneerson argued in opposition that it had been proved that certain men of genius descended from families subject to hereditary disease, while they themselves were often abnormal, quoting the cases of Dostoevski and Nietzsche. The doctrine of mental eugenics meant the elimination of outstanding personalities and in the end the lowering of the intellectual standard of humanity. The increase in mental disease, notwithstanding the progress of medical science, was due to the increased nervous tension of modern life, and suggested a remedy in the improvement of material and social conditions. The surest eugenic measure was the instinct of love. Any other detracts from the dignity of man and deprives him of all his faculties of intellectual and moral progress. The proposals of the report were also criticized by Prof. Beck of Prague, who pointed to the contradiction inherent in the application of all racial doctrine and theories of "the blood", which while imputing insubordination to the law of the blood, maintained that a blind racial destiny imposed a determinism, which denied freedom of will to adopt such measures of eugenics as would foster the intellectual advancement of the species—the voluntarist conception of the problem.

Among other communications may be mentioned Mme. Hauser (Amsterdam) on the effects of environment on the sounds of language, and Dr. Schneider's report on biometric investigations among the Otomi of Mexico. The proceedings of the section closed with a full session devoted to consideration of a masterly report by Mlle. Weinberg on "Differential Biometry and Biotypology in the Classification of Individuals and Groups".

The Central (Native) Medical School, Suva, Fiji

By Sir James Barrett, K.B.E.

THE major problem in the attempt by a civilized nation to develop people who, by our standards, are regarded as backward, is the control of disease and the preservation of health.

It is difficult of solution for several reasons. The native is not inclined to co-operate, as he does not understand—and finds it difficult to understand—the mode of thought and the technique of the European medical officers. The employment of many European medical officers is economically impossible, hence the training of the native himself is essential. Knowing the language, customs and mode of thought of his countrymen, he can effect changes which otherwise would be out of the question. For these reasons the Central (Native) Medical School at Suva,

Fiji, furnishes a great object lesson, since it represents a sincere and successful attempt to apply the principles of Western medicine to Polynesians, Melanesians and (now) Indians in the South Pacific. Like most British institutions, the growth has been gradual and the adaptation to needs has been effected as occasion arose.

The Principal Medical Officer in Fiji in 1885—Dr. Coney—obtained the passage of an ordinance providing that any native student who had received hospital training and practice for three years and been examined in medicine and surgery might be enrolled as a native medical practitioner. There was no medical school building and the training was effected at the Colonial Hospital, Suva. In 1900 a

lecture room and a hostel for the residence of students were built, and with diagrams, models, text-books and lectures a more comprehensive system was organised. At this date there were about twenty practitioners. In 1918 there were forty-eight, who did fine work in the influenza epidemic of that year, but during which eight of them lost their lives.

In 1923 the hospital was rebuilt and re-organized and called the Colonial War Memorial Hospital, and with subsequent development has become an excellent and extensive institution. Students from other Islands than the Fiji group were admitted and the School became a central school for the Western or Southern Pacific.

At this stage Dr. Montague was Chief Medical Officer, and in co-operation with Dr. Lambert—director of the Rockefeller Foundation in the South Pacific—a notable development took place. A School was built with the generous aid of the Foundation, containing lecture rooms, dissecting rooms, chemical and physiological laboratory, library and museum. Accommodation was provided for forty resident students. Quite recently the Foundation has given an excellent pathological, bacteriological and biochemical block and a post-mortem theatre. It is hoped that this laboratory will become the centre of investigation for scientific study in the South Pacific. The staff of the School consists of a whole-time tutor and fourteen honorary lecturers. The teaching in the old school was in the Fijian language. In the new school good knowledge of English is required of all students, and an entrance examination on the basis of the New Zealand proficiency examination is required. The course of study until 1931 was of three years' duration, but it was then increased to four years' and post-graduate courses came into existence.

Whilst this development has taken place, the training of native nurses was organized on a three-year basis, and in 1935 there were fifty-five nurses in the department and stationed throughout Fiji. It is hoped to make the hospital a central School for Nurses in the South Pacific by similar methods to those adopted in the Central Medical School. Such then is the mechanism of this really useful institution.

The students are divided into two groups—junior and senior. The junior course occupies 1½ years and the senior course 2½ years. The junior course covers chemistry, physics, biology, anatomy and physiology with some voluntary out-patient hospital work. The senior course includes medicine, surgery, public health and the smaller clinical subjects, including the study of diseases of children, diseases of the eye and some dentistry. The number of students in 1935 and their source is set out in the accompanying table:

	1st year	2nd year	3rd year	4th year	Post- graduates	Total
Western Samoa	3	—	—	1	—	4
Eastern Samoa	1	—	—	—	—	1
Tonga	1	—	1	2	—	4
Gilbert and Ellice Islands	1	—	1	2	1	5
Solomon Islands	1	1	1	1	—	4
New Hebrides	—	1	—	—	—	1
Nauru	1	—	—	—	—	1
Cook Islands	2	—	—	1	—	3
Fiji—Fijians	4	—	5	5	1	15
Rotumahans	—	—	2	—	—	2
Indians	1	—	1	—	—	2
	15	2	11	12	2	42

During the year there were 40 students in residence at the two dormitories. The two post-graduates in the above list are qualified native medical practitioners, and do not reside in the students' dormitories. The 12 Fijian students who reside in the smaller dormitory are required to keep their rooms and grounds in good order. The remaining 28 students who live in the large dormitory are expected to keep their own bedroom tidy and clean, but an Indian servant is provided to assist in the general management of the other rooms and the surrounding grounds. The students' dining-room is in the large dormitory, so that during the continuous rainy weather, which lasted for about six months during 1935, the Fijian students were put to great inconvenience as the two dormitories are about a quarter of a mile apart.

Recently Dr. Hoodless, the medical tutor, in answer to some questions of mine, furnished the following information:

Roughly, the 40 students at present (October, 1936) at the Central Medical School, include 19 Polynesians, 6 Melanesians, 6 mixed Polynesian and Melanesian, 7 mixed European and Polynesian and Melanesian, and 2 East Indian. The Polynesian students win most of the prizes at class and yearly examinations, but this is due to their numerical ratio, 19 out of 40 students: and also due to the fact that the mission and Government schools in the Polynesian islands are much superior to those in the Melanesian islands, so that the Polynesian students enter the Medical School with a very satisfactory preliminary education while the pure Melanesian students come here with very little elementary education. Indian students generally speaking are very good at book learning, but they do not make the same success at practical work. For steady regular work and good progress in medical knowledge, the mixed type of student, part Polynesian, is perhaps the most successful of all, but here again there are other factors at work.

Supervision of the students when they return to their own Islands is entirely in the hands of the local administrations. For Tonga, the Gilbert and Ellice Islands, and the Solomons, the native medical practitioner ordinances in each Administration can be controlled from Fiji through the Western Pacific High Commissioner, who is also Governor of Fiji. For Eastern Samoa (U.S.A.), Western Samoa (N.Z.), Cook Islands (N.Z.) and the New Hebrides (Fr. and Brit.) the position is different. The success of the native medical practitioner system in each of these Administrations depends on: (a) A sympathetic understanding and control from the Administration concerned. (b) A close personal and very sympathetic understanding from the European medical officers in any of these Administrations in regard to the native medical practitioners sent back from Suva to that Administration. (c) A continuously developing *esprit de corps* among all the qualified native medical practitioners far and wide in the South Sea Islands. This is obtained through the *N.M.P. Journal*, personal correspondence, and occasional post-graduate courses.

Pensions have been granted for retired native medical practitioners in Fiji only. The native medical service is only a few years old in the other Administrations, and the question of retirement on pension has not yet arisen, nor is it likely to arise for another fifteen years or more. It is anticipated that pensions will be granted in Tonga and in Western

Samoa, but in the other Administrations it is probable that increased salary and allowances will be given during the actual period of service and that no pensions will be granted.

The native medical practitioners receive salaries varying from £60 to £150 per annum, which apparently meet their wants adequately. They are medical officers and do not seek private practice as we understand it. Their journal, *The Native Medical Practitioner*, is an excellent publication which will interest any European practitioner.

In the *Tropical Diseases Bulletin* of November 1936 a detailed account of the working of the Central School is published by Dr. Clunie (Medical Superintendent of the Colonial War Memorial Hospital, Suva) and Dr. McGusty (late Inspecting Medical Officer, Fiji). The Islands served contain about 500,000 people, and at present there are 84 medical practitioners distributed as follows: Fiji 56, Samoa (Western) 9, Samoa (Eastern) 0, Tonga 4, Cook Island 2, Gilbert and Ellice 10, Solomon Islands 2, New Hebrides 1, total 84; native obstetric nurses, Fiji, 47.

Their conclusion is as follows: "Taken individually the Administrations participating in the Native Medical Practitioner scheme have not the means to embark on elaborate enterprises to provide adequate medical services, but by a pooling of their resources, as is now the case at the Central Medical School, it is felt that they will be able to elaborate a common form of health organization that will bestow further benefits on the native peoples. In Fiji the system has proved successful after a long and searching trial, and if it is too early yet to claim the same success with regard to its more recent ramifications into the other Pacific Administrations, the similarity of conditions and the favourable reports that are coming to hand appear to provide full justification for the confidence which those of us who are in the closest touch feel with regard to the future of the Native Medical Practitioner in the Pacific. As the system becomes more permanently established everywhere

it will suffer progressively less from the effects of destructive criticism, but there will always remain the danger that some over-enthusiastic supporters may lose sight of the fundamental cause of its success and in a misguided attempt to raise the status of the Native Medical Practitioner may defeat the purpose for which the school was created, namely to make a health service available to these native peoples at a low cost and in the form that is most easily assimilable by their society."

The School is administered economically, the average cost per student being about £75 per annum; that is, total cost about £3,000 per annum. Amongst the many tributes to the efficiency of the School place must be given to the observation of Prof. Buckmaster and Dr. Wright made after a visit to the School when returning to England in 1931 from Australasia. Their comment was as follows: "The Hospital and Medical School at Suva for Natives of Fiji, Samoa and Other Islands is really a wonderful place to find in the South Pacific. We not only saw all over the Hospital, but conducted a short class in anatomy and physiology in the School and both thought the students equal to what we might have expected to find in an ordinary Medical School in London. Indeed we were both astonished at the information they had acquired. I ask how many Englishmen know anything about this remarkable Hospital in Fiji?"

In conclusion I have one caution to emphasize. If enthusiastic people try to extend the course and to increase the expense, much damage may be done in seeking something economically impossible. There is, I am glad to say, no evidence at present of any such intention. Depopulation has ceased in Fiji and with prudent administration the Central School may prevent depopulation in the other Islands. I am very grateful to Dr. A. H. B. Pearce, Principal Medical Officer, Fiji, and his staff for the information furnished on several visits, for the personal contact obtained with these fine young men and for many reports.

The Radio Exhibition at Olympia

THE annual radio exhibition at Olympia, which this year was held on August 25-September 4, is generally a partial disappointment to those interested in the scientific and technical aspects of broadcasting, as it is usually quite difficult to ascertain what technical progress and improvements are being displayed. The exhibition is largely an elaborate display of the external cabinets, although most firms nowadays provide simple means for inspecting the internal construction and layout of the receiver itself. This year there was abundant evidence to show that most manufacturers have realized that the modern broadcast receiver has to take its place as an article of domestic furniture, and as such it must not be made especially conspicuous by its curious shape and appearance. Another notable advance in what may be termed the external features of the receiver is constituted by the enlargement of the tuning scale and its ease of operation. There is, however, still room for greater uniformity in the location of the control knobs among receivers of different makes.

In order to appreciate the improvements made in the internal portion of broadcast receivers, the visitor to the exhibition was fortunate in having as a guide the detailed reports given by such technical journals as the *Wireless World*, which has published three special show numbers on this occasion. A general survey of this year's exhibits of the various manufacturers indicates that many fundamental features of the broadcast receiver have become sufficiently stabilized for the designer to concentrate upon the steady improvement of detail. The great majority of receivers now manufactured are of the superhetrodyne type, since this provides both the sensitivity and the selectivity required by modern broadcasting conditions. The selectivity has now generally been made adequate by the incorporation of a properly tuned amplifying stage operating at the incoming signal frequency. A noteworthy advance this year is the incorporation of a correctly designed short-wave range as a standard feature; and the division of the short-wave broadcasting band into

two ranges is a factor which adds considerably to the ease of operation of the receivers so fitted. Those familiar with difficulties of tuning in short-wave stations will also appreciate the improvements in the mechanical portion of the slow-motion drive to the tuning condensers, as well as the large easily read scale which is generally provided nowadays. Several of the receivers shown at the exhibition were provided with a wave-length range in the ultra-short wave band, so that they may be used for the reception of the sound portion of the television programmes.

This year's exhibition was not so conspicuous as some of the previous ones for radical modifications in the types of valves incorporated in receivers, but two points here are worthy of note. The development of the tetrode output valve has caused the rating of most mains-operated receivers to be raised from the previous value of 2-3 watts to 5 watts or above. Secondly, one manufacturer of an all-wave superregenerative heterodyne receiver is experimenting with the use of the Harries all-stage valve. In this receiver all six valves are of the same seven-electrode type, the valves being adapted for their functions in the various stages by suitable external connexion to the electrodes. It will be interesting to observe the results of this innovation, since the advantages of using the same type of valve in any position in a receiver are self-evident.

In the case of battery-operated sets, the main problem all the time is to obtain sufficient output of good quality without overloading the normal high-tension battery, the size of which has now become fairly well standardized. Although the output from such receivers seldom exceeds half a watt nowadays, considerable improvement in acoustic sensitivity has been attained by the use of improved magnetic alloys for the small permanent magnet loud-speakers generally employed in such sets. There is ample evidence that the portable wireless receiver has still a wide field of service, and the attractions of several of this year's models are enhanced by the inclusion of a properly designed short-wave range.

Probably the most interesting feature of Radiolympia this year, from a technical point of view, was the fact that more than a dozen manufacturers showed fully developed television receivers suitable for the programmes now regularly provided from the London station. Direct reception of these programmes was carried out at the exhibition, and facilities were provided for each firm to give demonstrations to the public under comfortable viewing

conditions. So far, little uniformity is noticeable in the design of the television receivers produced by the different manufacturers, although they naturally all employ the cathode ray tube for the reproduction of the picture image. There is a tendency to favour the use of the superregenerative heterodyne receiver, although in a number of sets the amplification is carried out at the ultra-high frequency employed for the television service. There is as yet no uniformity in the methods employed for the control of the electron beam in the cathode ray tube, as both magnetic and electric methods are employed for focusing and deflection. One of the most interesting television receivers exhibited employs a tube of only 4 inches diameter; the image produced on the fluorescent screen of this tube is projected on to an etched glass screen giving a picture of size 20 in. $\times$ 16 in. The more normal method, however, is to produce the final picture on the screen of the cathode ray tube and to view this either directly or through an inclined mirror. The normal size of picture for receivers priced at 60 guineas upwards is about 10 in. $\times$ 8 in.; but some cheaper receivers are now available giving a picture size of about 7½ in. $\times$ 6 in. With the view of obtaining the utmost economy in the production of a television receiver, one type shown provides the circuits for the vision signal only, a normal broadcast receiver being required in addition to reproduce the sound accompaniment. In this way, a receiver giving a picture about 6 in. $\times$ 4½ in. in size can be obtained for about £35. This is a development likely to be worth exploring in the attempt to produce a television receiver at a price sufficiently low to appeal to a large number of listeners who already possess a normal broadcasting receiver.

In concluding this review of the exhibition organized by the Radio Manufacturers Association, mention must be made of the interesting museum provided to illustrate the evolution of the modern broadcasting receiver, and of the extension to the television field of the interesting demonstrations provided by the Post Office to illustrate the deleterious effect of various classes of electrical interference on the conditions of broadcast reception. Finally, it must not be forgotten that one of the most popular attractions of Radiolympia is the provision by the British Broadcasting Corporation of daily variety concerts in a specially constructed hall, which this year contained accommodation for an audience of more than 5,000.

R. L. S.-R.

Isotopes of Strontium

WORK on the isotopes of strontium has recently been reported by Mattauoh, and by Hahn and co-workers. Mattauoh (*Naturwissenschaften*, 25, 170; 1937) has determined the packing fractions of the isotopes ^{86}Sr and ^{87}Sr by the doublet method, using $^{31}\text{SiF}_3$ and $^{32}\text{SiF}_4$, respectively, for comparison. Using the data of other workers for the masses of ^{28}Si and ^{29}Si , the packing fraction of ^{86}Sr is found to be -8.7 ± 0.3 , and its mass 86.924 ± 0.004 . The packing fraction of ^{87}Sr is -9.0 ± 0.5 , and its mass 86.922 ± 0.004 .

The radioactive transformation of rubidium into the strontium isotope of mass 87 has been investigated by Hahn, Straßmann and Walling (*Naturwissenschaften*, 25, 189; 1937), who examined the strontium occurring

in a mica from Silver-leaf mine, Manitoba. The mica was comparatively rich in rubidium (containing 2-3 per cent of it), but contained only a very minute amount (a few hundredths of a per cent) of alkali earth metals. Careful treatment of the mineral resulted in the isolation of 250 mgm. of strontium carbonate. If rubidium breaks down by radioactive disintegration to give strontium, it would be expected that the product of disintegration would be present in the mineral in comparatively small amount. As alkali earth metals were actually almost entirely absent, it is very likely that the small quantity of strontium present was derived from this disintegration. The geological age of the mica is estimated at

500-1,000 million years, whilst the half-life period of rubidium is between 2×10^{11} and 4×10^{11} years.

An investigation of the isotopic constitution of the strontium from the mineral throws much light on its origin. This has been carried out by Mattauch (*Naturwiss.*, 25, 189; 1937), who finds the strontium to contain 99.97 per cent of the isotope of strontium of mass 87. It is therefore very probable that the β -radioactive disintegration of ^{87}Rb results in the formation of ^{87}Sr . This is in agreement with the rule that stable isobars of neighbouring elements do not exist. A rough estimate of the quantity of strontium produced during the life of the mica shows that the half-life period of radioactive rubidium is more nearly 2×10^{11} years than the upper limit mentioned above.

University Events

CAPE TOWN.—Prof. A. W. Falconer has been appointed to succeed Sir Carruthers Beattie as principal and vice-chancellor of the University. Sir Carruthers Beattie will retire at the end of the year. Prof. Falconer is at present professor of medicine in the University.

CAMBRIDGE.—T. R. C. Fox, of Jesus College, and J. Diamond, of St. John's College, have been appointed demonstrators in engineering.

Dr. R. A. Lyttleton and M. H. L. Price have been appointed Faculty assistant lecturers in mathematics.

J. Hart-Mercer has been elected to the Gwyneth Pretty studentship and to the Nita King scholarship.

At St. John's College, a Strathcona exhibition for physics has been awarded to R. E. B. Makinson, University of Sydney, and a Hutchinson studentship for zoology to J. H. Sang, University of Aberdeen.

Science News a Century Ago

J. D. Forbes among the Dolomites

IN the course of his Continental tour of 1837, J. D. Forbes after leaving southern Germany explored the Tyrol and early in September entered the then little-known 'Dolomite' country, proceeding in the direction of the peak of Marmolata. In his journal, under the date September 14, he said: "This morning, whilst warming myself dreamily during the rain at the kitchen fire at Cavalese, I got an excellent geological lesson from the boiling of certain thin porridge made of Indian corn (polenta) and milk. The air-bubbles disengaged during the process formed the most beautiful elevation craters, often with little interior ones, formed by the immediate sequence of another bubble at the same point. . . . I walked from Cavalese to Vigo, in order to understand fully Von Buch's section of the adjacent beds of rock, and in this I succeeded beyond my expectations. But the strata of limestone and sandstone do not all dip towards the axis, as he has represented, but some from it, and with evident disturbance. I went in search of minerals to a dealer's, but only found some very indifferent specimens.

"The scenery from Vigo to Campedello, and from that to Canazea, is in the highest degree striking—in fact, I know nothing of its kind to compare with it: one is entirely surrounded by jagged peaks of

dolomite. The amazing crags of the Lang Kofel come into view near Campedello, and afterwards the magnificent outworks of the Marmolata and Sasso di Val Fredda are seen in all their majestic beauty. As I wished to examine the Lang Kofel more minutely, as well as Von Buch's sections between Gröden and Colfusco in the Abteier-Thal, I availed myself of a tolerable horse track which wound through the forest, and after passing close under the precipices of the Lang Kofel, entered the Grödener-Thal. . . ."

Prof. William Ritchie, F.R.S.

ON September 15, 1837, William Ritchie, the professor of natural philosophy at the Royal Institution and also in University College, London, died at the age of forty-seven years. Born in Scotland in 1790, he was educated for the ministry and became Rector of the Royal Academy of Tain, Ross-shire. Having saved money he went to Paris, where he attended the lectures of Thénard, Gay-Lussac and Biot and on his return to England became known to Sir John Herschel. Papers he contributed to the Royal Society on a differential thermometer and radiant heat brought him into notice, and in 1829 he was given the professorship at the Royal Institution and in 1832 that at University College. He published papers in the *Philosophical Magazine* and other periodicals and made researches in electricity and electric magnetism. He was also known as a skilful experimentalist, and at one time was engaged on experiments connected with the manufacture of glass for optical purposes.

Animal Magnetism

THE *Gentleman's Magazine* of September 1837 gives the following information: "At the North London Hospital, M. Duportet, the French professor of animal magnetism, lately performed some experiments before a party. He commenced his operations on a young girl, about 17 years old, an inmate of the hospital, who has been ill for some time, but who is at present almost convalescent. She was seated in a chair in the middle of one of the wards, and M. Duportet seated opposite to her commenced the operation of magnetizing, which is done by waving the hand up and down in a perpendicular line before the face and body, as closely as possible without almost actual contact. After these motions of the hand had been continued for some minutes without effect, the professor, nothing disconcerted, left off, and another patient was introduced, who, we understood, had been operated upon more than once, deriving, it is stated, some benefit in her health. She was a young woman named Lucy Clarke, who having for some time past been subject to epileptic fits, had been induced to come to the hospital from Tottenham, where she resided, that the experiment might be made upon her. As soon as she was seated Prof. Duportet commenced the waving of his hands, and in a few seconds an appearance of extreme drowsiness became evident to all who stood around his chair, and she frequently rubbed her eyes as children do when sleepy. She at length ceased to have the power of opening her eyes. The magnetizer, however, who had placed her under the spell, had the power also of restoring her to a state of wakefulness. This he did by placing his fingers on the centre of the forehead and drawing them asunder towards the temples, and afterwards waving the hand to and fro before her face."

Cholera in Europe

AN editorial in the *Lancet* of September 23, 1837, gives the following account of a pandemic of cholera at that time: "The cholera—that terrible epidemic, which after having exercised its ravages in all parts of the old and new world, seemed on the point of returning to the country which gave it birth, has again appeared raging with unabated violence not only in many of the southern States of Europe, but in some of the northern kingdoms, already more than once visited by the pestilence. Our readers are doubtless aware that the Asiatic cholera has been stalking along the Mediterranean shores of Europe for the last two or three years, and that, at the time we write, it has reached the capital of the Papal dominions. The progress of the disease through countries, the inhabitants of which are forcibly kept by their rulers in a state of ignorance, has been almost universally accompanied by disorder of the most serious nature."

"At Palermo the Governor has fallen a victim to the fury of a terrified and excited populace; and at Rome, if we are to believe the reports which have just reached us, the medical men are everywhere compelled to conceal themselves in order to avoid sharing the fate of several of their brethren, who are massacred during the period of excitement and consternation, which are produced at the onset of the malady. Marseille also has been attacked, for the third time, by the epidemic, which during several days carried off nearly 100 persons daily, and we are sorry to announce that the disease is spreading rapidly throughout the department of which that city forms the capital".

Societies and Academies

Paris

Academy of Sciences, July 5 (*O.R.*, 205, 1-98).

WOLFGANG DOEBLIN: The elements of a general theory of the simple constant chains of Markoff.

KENTARO YANO: Totally geodesic non-holonomic spaces.

MARCEL BRELOT: The best harmonic majorant of a sub-harmonic function.

RAPHAËL SALEM: A method of summation nearly always valid for Fourier's series of continuous functions.

NATAN ARONSZAJN: A theorem of the theory of analytical functions of several complex variables.

JEAN LERAY and LOUIS ROBIN: Complement to the study of the movement of an unlimited viscous liquid.

PIERRE VERNOTTE: Navier's equations and the dissipation function, in a hydraulic system. The thermal phenomena produced in the fluid by a rapid movement.

MAX THISSIM SOLIER, LUIS CASTAGNETTO and MARCEL SABATHÉ: The beats which accompany the formation of the alternate vortices of Bénard-Karman.

ANDRÉ LICHTENROWICZ: Extension of the Gauss-Whittaker theorem.

FRITZ LONDON: The quantum theory of the diamagnetism of aromatic compounds.

TH. DE DONDER and J. GÉHÉNIAU: The electronic model of Dirac's wave mechanics.

JEAN JAFFRAY: Observation of the stratified Geissler discharge in different gases at atmospheric pressure. Under certain conditions, described in

detail, stratification can be seen and photographed in Geissler tubes containing various gases at nearly atmospheric pressure.

FRANTZ PERRIER: The action of an electric field on an electrified insulator placed in air: the ionization of the latter.

ALEXANDRE DAUVILLIER: A universal counter. A modification of the Geiger-Müller counter, utilizing Richter and Geffcken relays with Neher and Harper mounting. The working voltage can be reduced to 300 volts, and the arrangement is suitable for measuring the intensity of the cosmic rays with captive balloons.

GEORGES AHIER: Christiansen filters. These filters are cells containing a transparent powder mixed with a liquid of the same refractive index. Study of the results obtained by varying the solid (flint and crown glass, fused silica, fluorspar) and the liquid.

CASIMIR JAUBERAN, LÉON GRILLET and MICHEL DUFFIEUX: The fine structure of the 5998.9 band of nitric oxide.

BERTRAND GOLDSCHMIDT: Study of the fractionation coefficients of salts possessing several hydrates. Study of the crystallization of barium acetate, with actinium X as indicator, and of strontium nitrate in presence of a trace of lead nitrate, with thorium B as indicator.

JEAN PERRIER: The equation of solubility of a pure substance forming a solid compound with the solvent. Control of a differential equation obtained theoretically by an experimental study of the system sodium iodide and acetone.

MARTIAL FÉLIX TABOURY and MARCEL BILLOT: The action of light on the Liesegang phenomenon.

HALDUN N. THREM: The oxidation of beryllium bronzes.

EUGÈNE CATTELAÏN and PIERRE CHARRIER: Contribution to the separation of the phosphoric ion and its estimation by a volumetric method.

JEAN BARON and PAUL LAFFITTE: The inflammation of acetaldehyde. Determinations of the temperatures of spontaneous inflammation of various ternary mixtures of acetaldehyde and oxygen with nitrogen, argon or carbon dioxide as diluent.

MABO TIPPENHAU, PAUL WEILL and BIANCA TOHOUBAR: The isomerization of cyclohexane methylene oxide into hexahydrobenzaldehyde, and the conversion of the corresponding amino-alcohol into cycloheptanone.

MARCEL SOMMELET: A particular mode of intramolecular rearrangement. Study of the decomposition by heat of $(C_6H_5)_2CH-N(CH_3)_2.OH$.

WERNER LIPSCHITZ and ERNST BÜDING: The *d*- and *l*-borneolglucosides.

PANOS GRAMMATIKAKIS: Some modes of hydrolysis of the substituted *N*-benzaloximes.

JEAN KANDEL: The hydrocarbons, halogen derivatives, ethers and esters corresponding to tetrahydroionol.

JOSEPH HOOK: Contribution to the study of substances with female hormone properties. The synthesis of 2-oxo-6,7,8,9-tetrahydro-4,5-benzooceanaphthene.

ANDRÉ GUILLEMONAT: The oxidation by selenious oxide of cyclohexene and of the 3 and 4 nonenes.

RAYMOND HOGART: The structural scheme of proustite and pyrrargyrite.

ANDRÉ VATAN: The comparative mineralogy of the sandy sediments of the Paris basin.

J. GOURCO and FRANCK BOURDIER: Pollen analysis and stratigraphical position of the Quaternary lignites of the Chambéry region.

THÉODORE MONOD: The geological constitution of the Mauritanian Adrar.

ALEXANDRE GUILLERD and **PIERRE ETRILLARD**: The persistence of fluorescein in the soil. The influence of ferruginous formations.

NICOLAS STOYKO: The periodicity in the irregularity of the rotation of the earth.

ARTHUR BRUNEL and **ROBERT ECHERIN**: The evolution of nitrogen, appearance of allantoinase and of urease in the germination of rust (*Agrostemma Githago*).

JOSEPH LEPÈVRE: The reversal of polarity produced in cuttings of *Salix*.

A. GUISSYSE-PELLISSIER: The presence of striated muscular fibre in the pulmonary arteries of the rat and the mouse.

MAURICE VILLARET, **HENRI BÉNARD**, **LOUIS JUSTIN BESANÇON** and **MILLE ANDRÉE ABADI**: The mathematical study of the kinetics of hæmolysis (kinolysis).

LIÓN KÉPINOV: The antiglycogenolytic action of insulin.

RENÉ SALGUES: Nutrient leucocytosis in reptiles in bad conditions of captivity.

JEAN LOHMELHUR: The adsorption of polypeptides by proteins. The behaviour of a solution of peptone.

Forthcoming Event

FARADAY SOCIETY, September 13-15.—General discussion on "Reaction Kinetics" to be held in the University of Manchester.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ASSISTANT LECTURER AND A DEMONSTRATOR IN ELECTRICAL ENGINEERING in the Imperial College of Science and Technology (City and Guilds College), Prince Consort Road, S.W.7.—Secretary (September 13).

ASSISTANT LECTURER IN ELECTRICAL ENGINEERING in the Manchester Municipal College of Technology.—The Registrar (September 20).

LECTURER IN PHYSICAL CHEMISTRY (Grade II) in the University of Bristol.—Secretary and Registrar (September 24).

SOIL CHEMIST for the Rubber Research Scheme, Agalawatta, Ceylon.—The Chairman (November 15).

INSPECTORS OF MINES in the Colonial Mines Service.—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1.

Philosophy of Early Education

IT was a foregone conclusion that so original and stimulating a contributor to contemporary thought as Mr. H. G. Wells—on this occasion we are almost invited to dub him Dr. H. G. Wells—would have things to say to Section L (Education) of the British Association calculated to provoke lively interest and discussion. Few listeners to his presidential address, many of whom were working teachers, could have adopted the language of Tennyson's "Northern Farmer": "An' I thowt a said whot a owt to 'a said, an' I ooom'd awa'y". The address was probably the better for being plain-spoken and provocative, for only so could Mr. Wells have been at his characteristic best.

Notwithstanding certain of his earlier experiences, Mr. Wells disclaimed the right to appear before his audience as a teacher, but preferred to introduce himself as a citizen at large. We take this to mean, what is indeed sufficiently obvious, that he is no expert in the art of teaching a class and managing a school, but that he claims the right of every intelligent citizen to criticize the results of the teaching and the output of the schools. Mr. Wells, however, is something more than a distinguished outsider. In his later phase at least, his writings have been those of a public teacher, who definitely sets out to show what young people ought to learn, if they are to become efficient citizens in the world of to-day. In other words, though he makes only a limited claim to talk about methods of teaching, he makes, rightly as we believe, an emphatic claim to talk about the content of teaching, the mental fare which the schools provide for potential citizens. His now famous "Outline of History", followed by the companion outline of "The Science of Life"—both of them necessarily written with much collaboration

—indicated his general view as to the kind of thing which an educated person ought to know. An acquaintance with the fifteenth chapter of his later book, "The Work, Wealth and Happiness of Mankind", further prepared one for the opinions to which he has now given full and forcible expression.

Mr. Wells began and ended his discourse with an almost solemn warning as to his self-imposed limitations. Questions of "drill, skills, art, music, the teaching of languages, mathematics and other symbols, physical training and development, and the rest", he deliberately placed outside the scope of his message. He felt he could be most helpful by concentrating on the sort of world picture we are presenting to young people, the essential framework of knowledge that should be established betimes in the normal citizen of our modern community. Whether he was fundamentally right in making all these exclusions from the essential framework is bound to be a sharply controversial topic, upon which we cannot fully enter. Suffice it to say that, according to Mr. Wells's judgment of educational values, the indispensable and irreplaceable structure of fact, the main beams and girders of which structure must be laid down, soundly or unsoundly, before the close of adolescence, should rest upon a threefold foundation of history, biology and geography, widely interpreted. These three, says Mr. Wells in effect, are the things that abide, and it is probably safe to add that in his view the greatest of these is history. But merely to quote these familiar labels would be to convey a totally inadequate idea of the length and breadth of his message.

What Mr. Wells means by history was already familiar to many, we hope to most, of his listeners. But he took the opportunity of denouncing once

more the sort of history which, at any rate until recently, has been taught in our schools, and in great measure accounts for that "crazy combative patriotism" which now threatens to destroy our civilization. Equally mischievous, he added, is the "furtive anti-patriotism of the leftish teacher". We suggest, however, that if Mr. Wells thinks that the sort of history denounced long ago by Herbert Spencer as "an obituary of kings and queens" and denounced later by John Richard Green as "drum-and-trumpet history", is still encouraged in our schools, he ought to make further inquiries. But the rest of his indictment is not so easily disposed of. He demands that school history should not only shed its insularity, its narrow nationalism and its contempt for the lesser breeds without the law, but that it should also be nothing less than the story of man's great adventure upon this planet. He claims that the archaeologists, and the historians of the rise and fall of empires, have provided far finer material for the mental equipment of modern youth than the 'hole-and-corner' history of a single nation. Here he will have many sympathizers and some severe critics. It was to be expected that this part of his address would receive special comment in the daily Press.

As regards the rest of the informative content of the curriculum as conceived by Mr. Wells, there will be general agreement with his ideas about the teaching of geography and simple economics; and indeed the modern teacher in schools of every kind has already gone a long way towards satisfying his requirements. The chanting of lists of capes and rivers is mostly a thing of the past. Where geography passes over into biology his strictures are just. Too many young people leave school ignorant of the wonderful story of life upon the earth, and equally ignorant of the working of their own bodies. But, asks Mr. Wells in effect, who is sufficient for these things? Certainly not, he declares, the present generation of teachers, two-thirds of whom ought to be re-conditioned or superannuated. Here again, having regard to the work done in summer schools and refresher courses, and the activities and publications of such large and important professional bodies as the Science Masters' Association and the Geographical Association, Mr. Wells should have made further inquiries. Also even a cursory examination of the text-books or reading-books now available for pupils of all ages, and exhibited by publishers at such meetings as those of the Annual Conference of Educational Associations, would have shown him

that the school books of to-day are vastly superior in every respect to those of the past.

The present position is that teachers as a body are more mentally alert and educationally active than ever they were. True, they may not be sufficiently intent upon the informative components of the curriculum as advocated by Mr. Wells, but their general attitude suggests plenty of room for hope. A generation ago, teachers were too much occupied in fighting for reasonable conditions of service. To a great extent they are now occupied in fighting for a better chance for the pupils.

But we wish to close these comments upon a note of appreciation. In one of his charming and vigorous philosophical essays, William James took up strongly the position that the great philosophic thinkers, however much they might try to sink the fact of temperament, could never succeed in doing so. The philosopher's temperament, declared James, "really gives him a stronger bias than any of his more strictly objective premises. It loads the evidence for him one way or the other, making for a more sentimental or a more hard-headed view of the universe". James proceeded to a broad classification of the great philosophic thinkers as the tender-minded and the tough-minded. The tender-minded he described as rationalistic (devoted to abstract and eternal principles), idealistic, optimistic, religious, free-willist and dogmatic. The tough-minded he described as empiricist (devoted to facts in all their crude variety), materialistic, pessimistic, irreligious, fatalistic and sceptical.

Not for one moment would we wish to apply to Mr. Wells every item in the second of these lists of adjectives. But he is one of the outstanding public teachers of our time, accustomed to take the broad philosophic outlook upon every problem that he touches; and if we were asked in which of the two categories we would place him, we should inevitably place him among the tough-minded. Few of our prominent thinkers could, for example, have got to the end of *any* sort of discourse on education without ever mentioning Shakespeare; but Mr. Wells forgot even to mention literature among the skills, etc., which he designedly excluded from his survey. Perhaps the British Association will next year seek to restore the balance by inviting one of the tender-minded brotherhood to address the Education Section. Meantime, the tough-minded Mr. Wells has given to all interested in education, something to think about and something to follow up.

Social Theory and Discipline

(1) *The Development of Sociology*

By Prof. F. N. House. (McGraw-Hill Publications in Sociology.) Pp. viii + 456. (New York and London: McGraw-Hill Book Co. Inc., 1936.) 24s.

(2) *Control in Human Societies*

By Prof. J. Dowd. (The Century Social Science Series.) Pp. xvii + 475. (New York and London: D. Appleton-Century Co. Inc., 1936.) 16s. net.

(3) *Ideology and Utopia:*

An Introduction to the Sociology of Knowledge. By Karl Mannheim. (International Library of Psychology, Philosophy and Scientific Knowledge.) Pp. xxxi + 318. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., 1936.) 15s. net.

CURRENT interest in the co-ordination of views on the social responsibilities of scientific workers gives topical interest to these three volumes. From different angles they are all concerned with the contribution which science could offer to the solution of social problems, and more especially with the conditions and principles of scientific thought in this field. In turn they give us a broad historical survey of the subject, a practical study suggestive of lines of research and a stimulating contribution to original thought on the underlying principles of social theory and discipline.

(1) About half of Prof. House's comprehensive but not exhaustive account of the development of sociology is concerned with the growth of sociology in the United States, and particular aspects and characteristics of that growth. As an introduction to the extensive literature of this field and as a reasonably balanced survey of the development of thought on social questions, it can be commended to the growing number of scientific workers who, in considering the social consequences of their work or the place of scientific thought and method in social and political questions, are anxious to gain some background of theory and experience.

Some such background is essential whether we are concerned with the theoretical aspects of social science or with its actual technique in the handling of social and political problems on scientific lines, if only because nowhere in the field of science is the question of values more important than in social problems. The historic background gives the clue to the meaning of many social phenomena and has a practical bearing in the interpretation of present-day conditions and problems. It is a fundamental objective in the preservation and transmission of the social heritage.

Prof. House is sometimes a little too comprehensive to be as lucid as is desirable in the furtherance of the objectives so clearly set forth in his introduction, and more judicious selection would have made the work less tedious and increased its value to the general reader and student. None the less, he has traced clearly the development of social thought from its origin until it commenced in the eighteenth century to take on a form which may reasonably be styled scientific, and in the first two parts of the book ample justice is done to writers and thinkers in this field both in Great Britain and in Europe. His survey of American conditions notes a number of weaknesses of social research in that country which have already received trenchant criticism from Flexner, but suggests that the belief that sociology has important practical bearings on problems of citizenship, personal conduct and occupational problems may lead to it being regarded less as a subject to be taught to college students. On the other hand, he is a little sceptical as to the prospects of the integration of sociology, economics, political science and anthropology into a social science.

(2) Prof. Dowd, limiting himself to the evolutionary or dynamic aspects of society, gives us a comprehensive study of the controlling influences which determine the evolution of human societies and enters a strong plea for research on the lines advocated by Prof. W. McDougall in "World Chaos". The major part of the book, following a brief discussion of the origin and functions of control in society and a summary of the development of control in such varied fields as industry, religion, art, government and family life, which he summarizes as a transition from paternal to social control accompanied by an increasing individual opportunity, incentive and development, is devoted to a highly stimulating examination of the varied factors which are involved in problems of control which confront us at the present time.

This is a book which anyone who is interested in social problems to-day, whether of leadership or of the re-integration of society under the impact of science, can read with profit and with interest. Prof. Dowd gives a well-balanced treatment of the many factors which complicate these studies. His chapter on control in industry is highly suggestive and is an admirable corrective to the narrow angle from which industrial administration is sometimes approached. We have in it one more plea that industrial efficiency cannot be dissociated from social efficiency. No individual can be inspired to do efficient work unless he has opportunity,

like the professional worker, to exercise his initiative, to share responsibility for the product and to receive recognition for his part in it, and the author lays a good deal of stress on the value of developing group loyalties and incentives of the professional type. He clearly believes that in the society of the future the motive of private profit will be insignificant and unnecessary.

Particularly to those who are concerned with the preservation of democracy and freedom of thought in the face of clashing systems of totalitarian States and social organization should this study make its appeal. The author never fails to recognize the need for discipline, and whether he is concerned with order in the State, in industry, or in the religious institution, he regards its development as of the first importance. Recognizing the fundamental principle of discipline that loyalty to group ideals and standards progresses from the smaller to the larger fellowship groups, he points out that the very existence of dictatorship is a confession of failure to engender the primary loyalties. Discipline, however, is not mere conformity to a fixed standard, but the acceptance of some ideal or principle as the determining influence in conduct and action.

This study of social control is in fact primarily a study of the meaning of liberty and its preservation. The ultimate object of social control is to facilitate the flowering of whatever genius or talent the individual may possess, and the main purpose of the book is to discuss the principles which may be applied in the development of a social order in which the individual can best express his personality and in which human relations may be most felicitous. This can only be achieved as a measure of discipline is accepted, at least sufficient to prevent a relapse to the social chaos which demands paternalism for its correction. Scientific workers at least should respond to the plea for the acceptance of group disciplines and larger loyalties, which will enable the individual to resist transient appeals likely to throw him out of his social orbit, no less than to the plea to enter on the wide fields of research now open to us.

Prof. Dowd makes many wise observations suggestive of lines of thought or study in respect of such matters as recreation as a social function, the relation between physical, moral and social efficiency, and professional or other occupational ability, or the growing significance of the service motive in industrial and business enterprise. He believes that if private business cannot be organized primarily to serve the public, it must give way to some form of State control, and he directs attention to the difficulty of effective discipline for citizenship if conditions are perpetuated which overstimulate man's desires for material possessions.

(3) Mannheim's work is scarcely one for the general reader, but is unquestionably the most significant of the three works as a contribution to the theory of sociology. Even in his discussion of the relation between social theory and political practice entitled "The Prospects of Scientific Politics", the author eschews the practical side and is concerned essentially with the fundamental principles by which effective action is determined. If, however, the book is primarily one for the specialist, apart possibly from the fifth section, which is little more than a scientific outline of the sociology of knowledge, written essentially as an article for an encyclopædia, it would be unjust to suggest that even the general reader will not find stimulating and suggestive passages in this work.

Prof. Mannheim lays a welcome stress on the necessity for precision of thought and on the interdependence and sensitivity to change and varying emphasis in the meaning of words. Thought, he points out, is a particularly sensitive index of social and cultural change, and few things have hampered progress in the development of the social sciences more than the loose and inaccurate terminology so often employed. Moreover, it is a rapidly changing intellectual world which makes possible the effective criticism of ideas and values formerly regarded as fixed. We need continually to recognize that every point of view is particular to a certain definite situation, and must be ready to determine by analysis the nature of this particularity. Knowledge is distorted when it fails to take account of the new realities applying to a situation, and when it attempts to conceal them by thinking of them in inappropriate categories. One of the weaknesses of the cultural sciences to-day is that they view their knowledge and formulate their problems abstract and torn from their concrete settings. To recognize more clearly this confusion is an enrichment rather than a loss, for the way out is to be won by the gradual extension and deepening of our insight and by careful advance in the direction of control.

The plea for fundamental thinking does not, however, lead Prof. Mannheim to understate the necessity for practical politics, though he does not attempt to elaborate even programmes for research in such fields. He clearly does not believe that the sphere of human activity on the mastery of which our fate depends will not yield its secrets even to scientific research. Nor is he to be numbered with those social scientists who believe that science must restrict itself to the causation of actual phenomena, that science is not concerned with what should be done, not with what ought to be but rather with what can be done, and with the manner of doing it. He has sought to trace the connexion between the actual interest groups

in society and the ideas and modes of thought they espoused. He has shown that these complexes of ideas which direct activity towards the maintenance of the existing order do not merely direct thought from the object of observation, but also fix attention upon aspects of the situation which might otherwise be observed or unnoticed.

Prof. Mannheim has thus given us an effective instrument for fruitful empirical research. He also insists on the acuteness of the problem of objectivity in the social sciences, and the interest of the observer in the observed and the overwhelming influence of beliefs about the ends of action. He shows clearly also that the factors at work in the human mind impelling and disturbing

reason are the same dynamic factors that are the springs of all human activity. The new discipline he outlines, which promises to give a fresh and profound understanding of social life, is supplemented by a clarification of some of the major moral issues of to-day. If the treatment is not always as lucid as might be desired, the book is none the less a significant contribution to thought in a field with which not merely the specialist but also all scientific workers and others interested in the deeper problems of to-day are increasingly concerned, and not the least of our thanks are due to the translators for the critical preface contributed by Louis Wirth.

R. BRIGHTMAN.

Fluorine Poisoning

Fluorine Intoxication:

a Clinical-Hygienic Study; with a Review of the Literature and some Experimental Investigations. By Kaj Roholm. Pp. xi + 364 + 47 plates. (Copenhagen: Arnold Busck; London: H. K. Lewis and Co., Ltd., 1937.) 20s. net.

FLUORINE intoxication from domestic or industrial causes is rare in Great Britain. For this reason the knowledge of its occurrence, causes and results is inadequate and restricted. In this recently published excellent survey in English of the clinical and experimental work on the subject, much useful information has been presented and the main points will be reviewed.

All fluorine compounds are toxic to man and animals. Taken orally, hydrofluoric acid solutions, sodium fluoride, hydrofluosilicic acid and sodium fluosilicate are highly toxic, calcium compounds being less toxic. Cases of acute poisoning from accidental and premeditated use are increasing. The compounds in the fatal preparations were either sodium fluoride or fluosilicate. Death occurred in all in less than twelve hours.

The cases of chronic poisoning can be divided into three groups. A small number of sporadic distribution are due to the use of insecticides for plants or animals, or rat poisons. A larger number occur in certain industries. Cryolite workers provide the largest number of cases, and it is the study of these that has been the important original contribution of Roholm's work. The other group of chronic cases represents the mildest but yet obvious form of fluorine effect, namely the 'mottling' of teeth. This occurs in localized regions, many instances of which have been recorded in

the United States. Mottled teeth occur in Italy, Spain, Holland and England (Maldon, Essex). In all these regions the effects on the teeth are similar in type but different in degree. The teeth can only be affected during development; they are chalky white and later they become stained with unsightly dark brown patches or 'mottled'. The cause is the presence of sodium fluoride in the drinking water. Even two parts per million fluorine in the water can cause this, and so calls for a change of supply.

In Morocco and the Argentine there is a form of chronic poisoning called 'darmous' which results from the extensive fluorine-containing phosphorite rock deposits. The cattle are badly affected with a form of osteomalacia. Feeding rock phosphate can lead to this condition. The use of bone meal has so increased that the supply is inadequate and rock phosphate is used instead. It is essential that the latter should be fluorine-free. Vegetation in the neighbourhood of chemical works emitting fluorine is affected and can be a source of danger to grazing animals. Similar results have followed volcanic eruptions in Iceland.

The distribution of fluorine has been considered. This part of the subject is not in a satisfactory state because of the difficulty of determination of fluorine, especially in animal material. Fluorine is not a necessary element in nutrition, nor is it present in more than a trace in average teeth; even mottled teeth only contain 0.05 per cent of fluorine.

Roholm's special work has been the study of fluorosis among workers in a cryolite factory. Cryolite (Na_3AlF_6) deposits occur in Greenland, are quarried and shipped to the United States and Copenhagen. In the latter the working of the

crude mineral to a fine pure state takes place. Those therein employed have been studied. The danger, one similar to that in silicosis, lies in the fine dust produced during the working. In all, sixty-eight workers, male and female, were examined (*questionnaire*, urine analysis and X-ray of limbs and pelvis). Gastric disturbances, palpitations, dyspnoea and rheumatism were the commonest complaints made by the workers themselves.

The X-ray examination revealed that intoxication was generalized, all bones being affected with a diffuse osteosclerosis accompanied by a calcification of ligaments. This was considered the most serious effect because it led to a decreased mobility of joints, in particular of the spinal column. The children of female workers in a few cases, where suckling had been prolonged, showed mottling of their permanent teeth. Experiments in which cryolite was fed to rats, pigs, calves and dogs verified the clinical findings, so that a clearer understanding of the workers' symptoms has been gained.

Convinced, then, of the toxic properties of fluorine, it is important to emphasize the sources of danger and possibilities of prevention. Danger lies in the manufacture and use of compounds of fluorine for insecticides, plant sprays, rat poisons and rock phosphate, for manure or cattle supplement. Prevention should aim at restricting the handling and hence the use of fluorine compounds. Where handling of minerals takes place, similar precautions are required as for silicosis prevention. Industrial waste containing fluorine should be converted to the least toxic compound, calcium fluoride.

My own inquiries in Great Britain have indicated that fluorosis has not yet been recognized as an industrial danger. Apparently fluorine minerals are not dealt with here. The danger, however, exists in the use of insecticides. A case of poisoning from accidental use of a chicken disinfectant was reported a little more than a year ago.

It is fortunate that a volume of such industrial, clinical and scientific value is available, in English, should the danger of fluorine intoxication become more common.

M. M. MURRAY.

The Living World

Science of Life Series

By H. G. Wells, Julian Huxley and G. P. Wells. Vol. 1: *The Living Body*. Pp. xi+223. Vol. 2: *Patterns of Life*. Pp. x+239. Vol. 3: *Evolution—Fact and Theory*. Pp. x+271. Vol. 4: *Reproduction, Heredity and the Development of Sex*. Pp. x+222. Vol. 5: *The History and Adventure of Life*. Pp. x+259. Vol. 6: *The Drama of Life*. Pp. x+316. Vol. 7: *How Animals Behave*. Pp. x+263. Vol. 8: *Man's Mind and Behaviour*. Pp. x+271. Vol. 9: *Biology of the Human Race*. Pp. ix+205. (London, New York, Toronto and Melbourne: Cassell and Co., Ltd., 1934-1937.) 4s. net each.

WE confess that we commenced to read with a certain prejudice, for we thought of the many distinguished authors who combined to write the "International Science Series" and cheaper "Primers" of still earlier date. Each wrote on his own speciality, and we assumed a certain virtue in this. We were sceptical in respect to this combination of literary capacity, of imagination and of learning, perhaps expecting that the latter on account of its 'youthfulness' would not be allowed its full play. However, we found ourselves reading Volume 1 on a train journey, and a volume has been our inseparable companion on all such for the last three months. We admit 'second

childhood' with its consequent loss of memory—and thus our reading gave us pleasure, point following point as to life and the methods thereof, in such definite order that they produced in us a happy restfulness, not the boredom that induces sleep. We found a well-authenticated story and could read without the worry of hybrid names, too often coined to glorify an author rather than of necessity. "We ought to have a name for it." "Why?" "Well, someone else will give one, anyhow!" Far from valid reasoning.

Our authors are so merged that they might have been one. They start with "The Living Body"—and it is the human body—a machine reacting to its varied surroundings, its driver a nervous system, and efficient so long as it is properly fuelled and cleaned, until in course of time it wears out. This leads naturally to the various 'patterns' affected by animals and plants, and then our attention is directed to the way in which they may have been evolved. We are not allowed to assume without ample evidence the overwhelming positions of evolution and natural selection, which sometimes are rejected owing to man's pride or fear. 'Heredity' is all-important here, reproduction, sex and the body changes as the individual grows—a happily written and clear series of essays.

"The History and Adventure of Life", weaving it into the conditions of each geological stratum, naturally appeals, but a map showing the proportional length of time of each period is not accessible where we want it, the table given devoting two-thirds of its length to man, its post-War column especially in our opinion being out of place; this we disliked, but we found the rest of the volume corrective and admirable. The "Drama of Life" is scarcely a self-explanatory title for life in the sea and on land and in its waters, and the swaying balance between the animals and plants in communities (ecology). To us this quite learned volume shows a curious lack of those personal and humorous touches which we had become accustomed to expect, and which recur in full measure in the consideration of 'behaviour'—a separate volume is devoted to man—and of the "Biology of the Human Race".

Our suggestion to parents who have children going to a university for any science course, and to teachers, is to use these volumes so that their children or pupils may be educated, not merely crammed. There are nine of them, one for the summer vacation before the first term, and then one in each vacation until the student sits for final honours. The examinational result—whether the student is biologist, physicist or chemist—a certain understanding, will be great, and the candidate will have something which will add permanently to his interest in life, and will help him in his relationship with his fellows and his community.

The series is a reproduction in convenient form of the volume entitled "Science of Life", originally published in 1929 and reviewed in *NATURE* of March 28, 1931; the separate and handy little volumes now before us have been appearing at intervals since 1934.

Theism Restated

The Philosophical Bases of Theism

By Dr. G. Dawes Hicks. (Hibbert Lectures.) Pp. 272. (London: George Allen and Unwin, Ltd., 1937.) 8s. 6d. net.

THE substance of Prof. Dawes Hicks' book was delivered as the Hibbert Lectures in 1931. The volume is designed primarily for the general reader, especially for those "who have abandoned the resort of basing their religious trust on a miraculously attested revelation", and for whom, therefore, the philosophic approach to religion is indispensable. The author admits that "philosophy can as little provide us with a new religion as the science of ethics can provide us with a new morality"; yet "a religious mind which has reflected upon the principles upon which its religion rests, is clearly an advance upon the religious mind which has not so reflected".

Dealing with what is known as the cosmological argument for the existence of God, we may note that Prof. Dawes Hicks rejects the idea of a creation out of nothing. "This idea of Nothing, in the sense in which we take it when we oppose it to that of existence, is a pseudo-idea, and the problems which are raised round it are pseudo-problems." Furthermore, "the idea of creation as an event which occurred at a definite date in the past calls to be unhesitatingly rejected. . . . If the notion of 'creation' is to be sustained at all it can only be in the sense of continuous creation—of a constant dependance of the world on the supreme Being". The gist of the argument for the existence of God from the existence of Nature,

is that "we are logically driven to acknowledge that there is a real existence beyond nature, unless we are prepared to rest in ultimate inexplicability, and to relinquish the attempt to frame any intelligible conception of nature at all".

In framing the teleological argument, Prof. Dawes Hicks stresses the point that Nature is strikingly adapted to human thought and reason, and in its very essence would seem to be intimately related to mind or intelligence. He alludes also to the work of the American biologist, Prof. L. J. Henderson, on the fitness of our material environment to support life. Countless other distributions of those three indispensable elements, carbon, hydrogen and oxygen, would have been no less antecedently possible, and yet we find "just *that* distribution, just *that* conjunction of properties, which is *fittest* for the maintenance of life".

Nor is the ontological argument overlooked by Prof. Dawes Hicks, and he does not admit that it was disposed of by Kant when he stressed the difference between 300 thalers in his mind and 300 thalers in his purse. For, after all, God is something very different from thalers, and as Anselm (who invented the argument) expressly affirmed, it was *only* in reference to the idea of the infinite that his argument had any significance. "This is an idea the content of which is wholly inexplicable by reference to finite, and therefore limited facts; and, accordingly, its mere presence in our consciousness is sufficient to establish the existence of a reality corresponding to it."

J. C. H.

Index to the Palace of Minos

By Dr. Joan Evans. With Special Sections classified in detail and chronologically arranged, by Sir Arthur Evans. Pp. vi+221. (London: Macmillan and Co., Ltd., 1936.) 31s. 6d. net.

PUBLICATION of an index in a volume separate from the main work would not in the ordinary course call for special comment, beyond note of the fact of issue. The index of "The Palace of Knossos" stands in a different category. The fact that the history of the Palace, as reconstructed in Sir Arthur's excavations, covers the whole of the Minoan age, and the scale in range and detail on which the index has been compiled, not only make it an indispensable aid to the use of the book, of which it is an appendage, but also constitute it a guide to the history of the period and its civilization at large.

Even that, however, does not exhaust its claim to be an essential tool of the historian and the archaeologist. The appearance of Sir Arthur's name as joint author is no mere formality; and for certain entire headings, distinguished by his initials, he has been entirely responsible. As these headings are all of first-rate importance in the archaeological and cultural sense, no one will quarrel with the author for having departed from the strict canons of the indexer. He has made each of them a chronological summary and survey of the subject with which it deals. The amount of detail which has thus been included may be judged from the fact that the entry for "pottery" runs to twenty-three pages, and many other heads of importance are treated on a like scale. The author's modest suggestion that the index may serve as a guide for those students who cannot afford the whole work does less than justice to its value and utility.

With a Spade on Stane Street

By S. E. Winbolt. Pp. xi+240+12 plates. (London: Methuen and Co., Ltd., 1936.) 10s. 6d. net.

STANE STREET, the Roman road running from Chichester to London, presents numerous problems, some of which have given rise to much controversy. The literature relating to it, in consequence, is considerable. Mr. Winbolt's contribution, however, cannot be regarded as in any way superfluous. Not only does he trace the road, field by field, in all its stages, but also he has submitted new and doubtful solutions for determining the line to the test of archaeological excavation, where the application of this method has been possible. His verdict, therefore, may be taken as final. It is unfortunate that excavation has been possible at two only of the *mansiones*, or road-side stations. At Ewell, between which town and London the road is usually regarded as non-existent, the author has boldly attempted a reconstruction of the Roman town upon lines which, while purely conjectural, are supported by cogent argument. Mr. Winbolt is a strong supporter of an early date for the road, and maintains that its importance was due not to military exigencies, but to its use for public and commercial purposes.

Organische Synthesen (Organic Syntheses)

Übersetzt und für deutsche Verhältnisse bearbeitet von Dr. Richard Amus. Pp. xii+586. (Braunschweig: Friedr. Vieweg und Sohn, 1937.) 45 gold marks.

IN the collected volume (1932) of the first nine annual volumes of "Organic Syntheses" (1921-31), several improvements were incorporated. New processes for several compounds were included, the descriptions of experimental procedure were enriched with small but important improvements, and indexes to reactions, substances and processes were provided. Such small but highly useful improvements as the statement of amounts of corrosive liquids and solvents in cubic centimetres as well as grams made a considerable difference in the practical utility of the volume. The descriptions are very full and references are given to the literature.

In the German translation the American materials and apparatus have been replaced by those obtainable from German firms and any necessary modifications of procedure introduced. By co-operation with the American editor-in-chief, Prof. Gilman, improved methods and corrections not to be found in the American edition have been introduced. The German edition will therefore be of interest to those who already possess the American volume, and it should prove most valuable to chemists who are more familiar with German than English. The paper and printing are good, and the translation appears to be careful and accurate.

The Future of Woman

By Anthony M. Ludovici. (To-day, To-morrow and After Series.) Pp. viii+152. (London: Kegan Paul and Co., Ltd., 1936.) 3s. 6d. net.

THIS little book forms a supplement to the author's "Lysistrata", which he now regards as too mild an indictment of feminism. As in his previous works, he maintains that one of the first and principal steps in the regeneration of the Western world is a masculine renaissance of man both as animal and as spirit. Feminism he regards as "nothing more than a government of odd people, by odd people, for odd people". In conclusion, he declares that there can be no solution of life's problems for normal women which leads them away from their normal function of nursing and training children.

Essentials of Modern Medical Treatment

By Dr. Vincent Norman. Pp. xvi+200. (London: Hutchinson's Scientific and Technical Publications, 1936.) 10s. 6d.

CONSIDERABLY smaller and less comprehensive than the well-known "Index of Treatment", to which numerous specialists have contributed, this volume, which is the work of a single author, is to be recommended to the practitioner and student for its lucidity, conciseness and up-to-date character, as well as for its considerably lower price. In addition to the eminently practical advice on treatment, a short account is given of the causation and symptoms of the various diseases.

Assam Origins in Relation to Oceania*

By Prof. J. H. Hutton, C.I.E.

IN choosing this subject I am not attempting to offer any definite solution to the problems of Indonesian migrations, but propose rather to examine one aspect of them in the hopes that I may elicit further information which may contribute towards the ultimate solution of what is really a complex of very difficult problems, as I feel that although a clearing up of the main question may be very distant, some analysis of the Assam side of the problem is perhaps possible.

Many parallels are to be found of one sort or another between Assam and Oceania, some of which were pointed out by Sir Henry Yule and by S. E. Peal in articles in the *Journal of the Anthropological Institute* in February 1880 and 1893 respectively, and others of which I myself indicated in an article on "Assam and the Pacific", in *Man in India* in 1924. In 1925 Henry Balfour pointed out cultural connexions between Assam and Indonesia in the matter of certain types of thorn-lined fish traps and, more recently, of fretted horn and shell ear ornaments.

It is fairly clear that identity of culture, in so far as it exists, is not that of a single culture, but rather of a complex of cultures in each case. It is certain that Assam may be able to throw some light on the Indonesian problem, as the stratifications can, at any rate to some extent, still be traced. The last immigrants are undoubtedly people of Kuki and Kachin affinities. There is a strong tradition among the Chins of the Arakan hill tracts pointing to their migration down the Chindwin Valley, no doubt throwing off parties which must have penetrated the Assam hills from the east on the way, after which one portion of the Kukis at any rate seem to have worked up northwards again from the Bay of Bengal, a movement which has barely ceased, if it has ceased, in the present generation. It would seem that the Kayans of Borneo probably formed part of the same movement. A tradition quoted by Hose and McDougall assigned the arrival of the Kayans in Borneo to the earliest years of the fourteenth century A.D., a date which fits well enough with Kuki and Tippera tradition.

Apart from such preceding migrations, of which there may have been many originating in movements in the Chindwin Valley caused by this southward Kuki-Kachin migration, and of which we probably have a memory in the traditions of

the Angami Lhota and Ao movements from Manipur westwards, the two previous cultures in the Assam hills seem to have been definitely matrilineal and to have belonged to two types. One of these—and presumably the later—seems to have been analogous to the present Khasi and Synteng cultures, the other to that of the Garo and of the Kachari of the Assam plains. The Khasi migration clearly came from the east, and the parallel culture in Tonkin to their earliest remains in Assam is dated by Coëdes to about the beginning of our era. The Garo-Kachari peoples seem to have migrated from the north bank of the Brahmaputra, and while the Kachari is now predominantly patrilineal, as the Garo is matrilineal, both may still be said to be in the process of change as the result of contact between two systems.

It is interesting to notice that in Madagascar the Vazimba, who preceded the Hova as immigrants, had a number of features in common with the megalith-using Khasi, not all of which were afterwards adopted by the Hova. The latter, for example, built in wood, whereas the Vazimba used stone. One may also observe that Hocart, writing on the early Fijians, is inclined to think that the more civilized community was swamped by barbarians before the more recent migration of Polynesians from the east. Undoubtedly the Naga tribes at present represented by the Konyak Nagas in the north and to a lesser degree by Kachha Nagas to the south of the Naga hills, are associated with a more civilized culture in some respects than that of the intervening tribes who have come up from Manipur, always excepting the Angamis, who are in many respects *sui generis* and who probably have incorporated a very great deal of the civilization which preceded them on their present sites.

One important feature of the Konyak tribes, shared, it is true, by their neighbours the Aos, and in a ruder fashion by the Sangtam, Chhang and Yimtsungr of the east, is the possession of enormous slit wood gongs to which I give the name 'canoe gong' on account of their shape. S. E. Peal was the first to report on these gongs, which he called 'canoe drums'; Prof. Henry Balfour calls them xylophones, and the only reason that I do not adopt his term is that I prefer to keep that name for the more usual type of xylophone consisting of a number of slats of wood giving different notes when beaten which is found among the Kuki, though not among the Naga tribes. These canoe gongs are the basis of an important cult intimately

* From the presidential address to Section H (Anthropology) of the British Association, delivered at Nottingham on September 3.

associated with head-hunting, and strongly suggestive of much that is associated with canoes in Oceania.

The true canoe gong with carved figure-heads and long hull like that of a dug-out is almost entirely limited to the Konyak, Ao, Chang and Sangtam tribes, and of these four undoubtedly the Chang and the Ao contain a large admixture of Konyak blood. The Sangtam only use a typical canoe gong in those villages which march with the Ao and Chang country. Farther south the shape is much less elaborate, and the Yimtsungr to the east of them used a mere hollow tree-trunk. South of the Sangtam tribe the canoe gong completely disappears except for the following instance: the Tangkul tribe use a remarkable form of gong, hitherto, I believe, unpublished, which might be described as resembling an inverted boat, the two ends of which are skeleton, while the centre part consists of the usual slit gong of more or less cylindrical type. The Angami use an unornamented wooden vessel of similar shape (without the skeleton ends) for the reception of liquor in bulk on ceremonial occasions, and one recalls Ellis's account of the man of Rurutu who came off to meet him "at a distance of two miles" from the island in a wooden food-vessel 6 feet long and 18 inches to 2 feet wide. A smaller slit gong of somewhat similar pattern, but much simpler, is used for scaring the birds from their fields by the Kachha Naga. Farther south again, the Zanniat Chins, who, unlike the other Chins, have a democratic organization, have a small slit gong not more than 6 feet long very like the Angami vat, while the Ngawn Chins use one of the same size not unlike the South American *teponatzli*, and put food in it on the occasion of a ceremonial dance.

It is interesting to observe that in South America the canoe gong appears to have developed independently from a hollow tree. It is, of course, possible that the canoe gong of the Naga hills has similarly developed from a tree trunk, but since we find no example of signalling by hammering on trees, we are perhaps entitled to argue that the process in Assam has been the other way, and that the smaller slit gongs, or the hollow tree trunks, used by some villages, are degenerate forms of the original gong which started as a canoe, and it is possibly significant that in the Kachin story of the great flood the two survivors escape drowning in "a large oval-shaped drum". On the other hand, it must be admitted that a simple form of slit gong occurs in Yunnan, as it does in Malaya and in Borneo, suggesting either marginal degenerations from a developed type in Assam, or possibly simple types from which the Assam one might have been elaborated. The real argument, therefore, for the canoe gong's being a survival from a real canoe

rests on its associations with head-hunting and a typical canoe culture.

Now the Naga canoe gong is closely associated with the men's house, and generally, if not kept in it, it is kept in an annexe. It is in some respects treated almost as an idol, and tremendous effort is expended on carving it and dragging it up to the village. All human heads brought in are first placed on the canoe gong, at any rate by the Ao, suggesting the Marquesan practice of decorating the prows of their war canoes with the skulls of their enemies. When the gong is dragged up to the village over wooden rollers, such as those used in launching a vessel, the blood of the sacrificed animals is poured on to it, and in the old days any stranger, whether friend or foe, who came to the village on the day when a new drum was dragged in, was killed in order that his head might adorn the drum and his soul inhabit it. Indeed, until a head had come in, or had been brought in for the drum, a fence was put round it which could not be removed, nor could the drum be beaten until the young men had been out and fetched a head to remedy the defect. This head was first laid on the new drum.

The parallel with Melanesian canoe practice is here very close. Codrington writes as follows: "In the eastern Solomon Islands, if no victim was met with in the first voyage of a new canoe, the chief to whom the canoe belonged would privately arrange with some neighbouring chief to let him have one of his men, some friendless man probably, or a stranger, who would then be killed, perhaps as he went out to look at the new canoe. . . . Further west also captives were kept with a view to the taking of their heads when new canoes were launched." He goes on to give an example in a footnote: "The chief of Ravu bought his *peko* [war canoe] . . . for a large sum of money. It was brought over secretly and put into a . . . canoe house, where it stood till a head should have been procured. . . . In the morning a single man came by . . . in his canoe . . . they caught and killed him, set up his head at the prow of the [newly bought] canoe and paddled back to Ravu with shouting and blowing conch shells."

Nowadays in the Ao country a mock raid takes the place of a real one, but even this chastened sacrifice leads to a great success in hunting and in agriculture. The Ao gong nowadays wears a necklace of basket balls representing heads. Real heads were never used in this way, although they were laid on the gong when first brought in. These basket-work ornaments perhaps afford a parallel with the carved head which formed part of the figure-head of the Melanesian canoe. The figure-head of an Ao canoe is generally in the form of a buffalo or gayal head, that of the Konyak tribes

an elephant, buffalo or hornbill head, but Peal, writing in 1893, remarks that the Konyak figure-head is (as depicted in his drawing) a crocodile, although "there are no crocodiles in these hills", and he points out that it is a familiar decoration in Indonesia and the Pacific. Although I have covered most of the ground visited by Peal in the last century, I have never seen any figure-head resembling the head of a crocodile, so that this tradition has apparently disappeared in the forty years since he visited the Naga hills.

It has occurred to me that the instruments used for beating the Naga canoe gong may conceivably be degenerate paddles. The ordinary type is more like the dumb-bell than anything, but often one end of the dumb-bell takes an ornamented form such as the hornbill's head, and in any event this 'dumb-bell' is not unlike a paddle in which the blade has degenerated to proportions similar to those of the handle.

F. E. Williams, writing of the Pairama ceremony in the Purari Delta in Papua, tells us that "when a successful hunt returned at evening the corpse of the victim was borne from the canoe to the *ravi* amid great enthusiasm. The men uttered that prolonged shout or roar which has a singularly exciting effect upon the listener, and rattle their paddles upon the sides of the canoes with the rhythm called *raruki raruki*. . . . On the following day the . . . hunter who first brings down the victim . . . is paraded in triumph through the village standing astride the canoe and balancing himself with a spear". It was formerly the custom of Meithei to signal across the Logtak Lake in the Manipur State in Assam by beating with their poles or paddles on the sides of their dug-outs as the Nagas do on a canoe gong, and I am further told by Mr. William Shaw, who served many years in the Manipur State, that some Kabui villages which have no canoe gongs still have the tradition of having used them once, while in Kabui Khulen village a sort of boat, with a high prow, is dragged in every year at the harvest festival "for all who have died in the past year". The best dressed of the young men rides on the boat, while there is a tug-of-war between the two clans of the village, one pulling at each end of the boat by ropes attached to pierced lugs left on when fashioning this dug-out, which is known as the *thingkhutong*—the plank to which a dead body is ordinarily fastened for burial in that village being called *thingkhu*. It must, I think, represent a boat or a boat-shaped coffin and be associated again with the fertility of the crops, so largely bound up both with the spirits of the ancestral dead, and of dead enemies, while the riding of the boat by the young warrior is reminiscent of the Pairama ceremony described by F. E. Williams.

Boat-shaped coffins are found occasionally in several of the Naga tribes, particularly in the Konyak country, where in one village at any rate they are associated with a tabooed chief, and it is worth noticing that a stone is put up by the Fijian 'spirit house' for each corpse brought in, precisely as the Konyak Nagas put up an erect stone outside the men's house for each head; and it is also remarkable that in one case, at any rate, there seems to have been a close association between the Fijian war canoe and the gong known as *lali*, since the chief Rokona named his war canoe Vatutulali, after his large gong.

The Samoans have a similar gong known as *longo*, the sound of which—according to Brown—will carry for twenty miles under favourable conditions. Brown also mentions that the Samoans struck the sides of their canoes with the handles of their paddles to mark time.

One more parallel is worth indicating in connexion with this subject. Writing in the *Journal of the Royal Society of Arts* of February 1937, La Valette illustrates the uptilted roofs of a branch of the Toradja tribe in Celebes, which he says are deliberately got from the prow and stern of a canoe, and are "bound up with the tribal traditions of their ancestors, who originally arrived from a country overseas to which the spirits of the dead must return". The roofs he illustrated are almost identical with forms common in one branch of the Konyak Nagas, east of the frontier of Assam.

I have elsewhere suggested a possible migration from Indonesia, and migrations from Indonesia to Ceylon and South India are placed by Hornell at about the beginning of the Christian era. I cannot help thinking that if, as I am tempted to believe, there was an Indonesian migration which swept upwards northwards into Assam before the Kukis came south, it must have been at an earlier date than that; at any rate there does seem to have been some expansion in many directions from Indonesia at a date which perhaps precedes the dates suggested by Coedes and Colani for the megalithic civilization of south-east Asia. It would be interesting to know how far the stratifications of cultures in Oceania will correspond to the apparent succession in Assam of an Oceanic canoe culture, a matrilineal megalithic culture and that of a more recent patrilineal one associated with the Kayan and Kuki. The principal point which I wish to make, however, is that the hill cultures of Assam correspond to other distant cultures or combinations of cultures, all of which appear to be marginal in distribution from an Indonesian centre, and that there is some ground for supposing that migrations of culture, if not of people, have taken place from some centre in or near the Indian archipelago in various directions, one of which terminated in Assam.

Noise and the Nation*

By Dr. G. W. C. Kaye, O.B.E.

NOISE ON THE ROAD

THREE reports on road transport noise have been issued by a Departmental Committee set up by the Minister of Transport, and the position is that for the first time in Great Britain a comprehensive attack has been made on the problem of road traffic noise. To this end, loudness measurements, many thousands in number, have been conducted under widely different working conditions, on the over-all noise of some 800 motor vehicles, both new and old, representing all the main types on the roads to-day. The results (at a distance of 18 feet sideways or 25 feet to the rear) mostly ranged between about 70 and 105 phons (the latter value corresponding to a noisy road drill). The Committee was led to propose simple running and racing engine tests which are associated under specified conditions with an 'over-all' noise limit of 95 phons (roughly equivalent to the noise in a tube train) for all vehicles in use on the road, and of 90 phons for new vehicles leaving the manufacturer's works.

The adoption of these noise limits, while making very moderate demands on most types of vehicles would, by ruling out the arch offenders, constitute a substantial contribution to the amenities of the road. In the meantime, the industry, which has already discovered that 'silence is saleable', has the matter well in hand, and indeed it is not unlikely that future developments will not only enable manufacturers to meet the proposed requirements with comparative ease, but may indeed enable the limits to be lowered as time goes on.

To assist the motor industry in this laudable object, the Ministry recently set up four noise-testing stations in different parts of the country. At each of these stations an N.P.L. noise meter is installed, and manufacturers are enabled to submit types of their products and so ascertain for themselves how the noise levels compare with the limits proposed.

The whole question will be further facilitated when the simplified objective noise meter, which has recently been developed by the National Physical Laboratory for the Ministry, is put on the market. Such meters, which will be checked against the Laboratory standard meter, should, when available in quantity, be of great assistance at such time as it may be decided to bring into force regulations for dealing with noise on the road.

(Continued from p. 449.)

THE ABATEMENT OF NOISE

There are two guiding principles when the question of noise abatement is being considered. One is that the degree of abatement of a noise in a particular locality need be no more than will conform to the background of noise which obtains in that locality. The other is that in a medley of noises, the loudest must be tackled first to achieve any appreciable benefit, after that the next loudest, and so on. This is illustrated by the fact that if there are two similar components and one is 10 decibels less intense than the other, the weaker one will contribute only half a phon to the over-all loudness.

The first line of attack on noise abatement, and in general much the most effective and economical, is to tackle an objectionable noise at the source, and find the best means of reducing the output as much as possible. The next step, possibly as a confession of failure, is to find a feasible method of confining or 'smothering' the noise in the place where it is generated. In either case we turn to the engineer for help, and we may anticipate that he is likely to be the more interested if he can see a potential demand from the public.

The path of a noise in its journey from source to hearer may be either *via* the intervening air or *via* a sequence of solid materials or structures. Experience has shown that the two effects require very different remedies for abatement. The study of the general problem of noise transmission is more complex than might be imagined, and some of the major difficulties are not as yet completely resolved. For the practical elucidation of the various factors involved, specially designed 'sound-proof' laboratories, such as those at the National Physical Laboratory, have proved to be necessary. Parenthetically, it may be mentioned that the N.P.L. acoustics laboratory, since its erection four years ago, has been so fully engaged in transmission and absorption work, mainly for the architectural profession and the building industry, that extensions are now in hand and should be available for use by the end of the year. Much research work on building acoustics is also being carried out for the Ministry of Health in connexion with slum clearance, and for the Architectural Acoustics Committee of the National Physical Laboratory and the Building Research Station.

To revert to the case of a non-suppressible noise, if most of the noise is transmitted by air, the best

remedy, should circumstances render it practicable, is some sort of sound-proof enclosure, the design of which may need careful attention both as regards weight and discontinuity of structure. There is, of course, no such thing as a sound-proof material, and success in sound insulation is largely a matter of design.

Certain large-scale operations may require 'sound-proof' buildings to mask them, the doors and windows of which should be heavy and close-fitting and preferably situated on the side remote from that where the noise is liable to be regarded as a nuisance. Doors and windows, particularly high windows and skylights, may require to be doubled and, in extreme cases, it may be necessary to employ double walls mounted on independent foundations. Buildings in which noisy operations are carried on should, if possible, be put under the lee of larger buildings, which may afford advantageous shielding to the locality. In the interior of noisy buildings, it is usually beneficial to the workers to divide groups of noisy machinery, so far as may be possible, into smaller units, each in its own enclosure. Appreciable benefit may also result from lining walls and ceilings with acoustical absorbent, so preventing the noise level from building up unduly.

In the case of structure-borne noises, the remedy is discontinuity somewhere in the structure either in the form of an air gap or as resilient material, for example, under the foundations of noisy or vibrating machinery.

Modern building design and materials do not provide protection from noises, whether from inside or outside, like the more solid houses of a generation ago. The noise problem is accentuated

in the case of the large blocks of flats which are being erected in all quarters, and which apparently are mainly adapted for quiet tenants who are prepared to conform in this respect to a landlord's reasonable requirements. The situation lies largely with local authorities, who should lay down building by-laws, setting forth minimum standards of acoustic insulation. The architect and builder have of necessity been driven from traditional methods of construction to meet the economic requirements and closer scientific designing of to-day. Discontinuity of structure and the use of massive and poorly conducting materials formerly provided defence against sound, but instead we now have monolithic structures which are not only thinner and lighter than the old, but also are composed of good conducting materials. The steel-framed and ferro-concrete building, cement mortar, hard bricks and plaster, to say nothing of a general ramification of central-heating, running water and other piping, have replaced the softer brickwork, lime mortar and plaster, wooden beams, joists and studding, and the localized piping of the older houses. No one pretends, of course, that we can go back to the old methods, but if we are to mitigate the noise nuisance in modern buildings, we must adopt measures which are best incorporated during the designing stage.

There is, too, another aspect which should be clearly appreciated, and that is, if sound insulation in buildings is desired, it has to be paid for. The public, at present enticed with a plethora of labour-saving devices by landlords of flats, has yet to learn that reasonable acoustic privacy is obtainable provided it is prepared to face a small proportionate increase in the rent.

Structure of Protein

THERE can be few problems of predominantly chemical interest which are being attacked by such a variety of methods of investigation as that of protein structure. This was well illustrated by the symposium on protein chemistry held on September 3 in Section B (Chemistry) of the British Association, in which the contributions ranged in subject from biochemistry to mathematics, each justifying its inclusion either by the addition of some significant fact to the total sum of knowledge or by the formulation of a stimulating hypothesis to account for facts which still await complete explanation.

The foundation of protein chemistry as we know it to-day has been laid by organic chemistry, which, chiefly in the hands of Emil Fischer and

his pupils, has provided not only detailed information concerning the composition of proteins, but above all the unquestionable demonstration of the peptide linkage as the predominant feature of their intramolecular structure. Moreover, through the development of improvements in peptide synthesis, particularly the carbobenzoxy method, organic chemistry has provided a wealth of material which has illuminated the mode of action of proteolytic enzymes and which now promises to throw light on the physico-chemical behaviour of proteins and even perhaps on their immunological specificity. These points were brought out by Prof. C. R. Harington (London) in opening the symposium, but he was at the same time at pains to emphasize that the peptide theory in its simplest form is

unable to account for all the properties of proteins, which can only be explained by the assumption of subsidiary linkages within the molecule.

The importance of the peptide linkage was further emphasized by Dr. K. Linderström-Lang (Copenhagen), who pointed out that this linkage is the only one known with certainty to be attacked by proteolytic enzymes. These enzymes, as is well known, may be roughly classified into the proteinases which attack complete protein molecules or their higher degradation products, and the various peptidases which attack peptides at points adjacent to free amino or carboxyl groups or both. Dr. Linderström-Lang directed attention to the interesting evidence which has recently accumulated that the true proteinases owe their peculiar specificity to the fact that they can only attack peptide linkages remote from free dissociating groups.

One of the greatest advances in the understanding of the physico-chemical behaviour of amino-acids and proteins is due to the zwitterion theory introduced by Bjerrum in 1923. The development of this theory and the evidence for its applicability to amino-acids was discussed by Dr. A. Neuberger (London), who laid particular emphasis on the good agreement to be observed between the experimentally determined dissociation constants of amino-acids and those calculated on the basis of the theory; evidence derived from dissociation constants of amino-acids other than α -amino-acids shows that such molecules exist in solution in a relatively unbent condition with the charged groups far apart, thus accounting for the high electrical moment required by the zwitterion theory. Dr. Neuberger proceeded further to demonstrate the fact that it is now possible to interpret the electrometric titration curve of a protein with reasonable accuracy in terms of the polyvalent amino-acids which it contains, the additional dissociating groups of these amino-acids being the factors which determine the electrochemical behaviour of the protein molecule as a whole.

The determination of the very large molecular weights of proteins is a matter of considerable difficulty, and no method has afforded more valuable information on this point than the ultracentrifugal method evolved by Svedberg. This procedure was described by Mr. J. St. L. Philpot (Oxford), and was illustrated by a very beautiful application in which the molecular weight of the enzyme xanthine oxidase was observed by its rate of sedimentation from a solution containing the enzyme system, methylene blue and iodate; the solution, at first colourless throughout, becomes coloured from the top downwards in the ultracentrifuge owing to re-oxidation of the leuco-methylene blue by the iodate as the enzyme is removed.

The remaining two contributions to the symposium were chiefly concerned with the nature of the subsidiary linkage in the protein molecule, which was referred to by the opener. The evidence to be derived from X-ray measurements was discussed by Dr. W. T. Astbury (Leeds), who recalled his well-known earlier work on the structure of the keratins, showing these proteins to be made up of bundles of peptide chains joined by subsidiary linkages which might be either the disulphide linkage of cystine or so-called hydrogen bonds or covalent linkages of unknown nature. It was pointed out by Dr. Astbury that X-ray measurements indicate a transition in structure from the stretched keratin or myosin molecule, through the partly folded molecule of unstretched keratin as it occurs in hair, to the completely folded molecule of the 'globular' proteins such as insulin. The evidence provided by X-ray measurements regarding the mechanism of denaturation of proteins was also discussed; it appears that this process certainly involves rearrangement and unfolding of peptide chains, but it seems to the present writer at least that the real nature of the phenomenon remains as obscure to physicists as it is to chemists.

Of the various theories of protein structure which have been proposed from time to time, few are of greater interest than the 'cyclol' hypothesis advanced on geometrical reasoning by Dr. D. M. Wrinch (Oxford). This theory, which has already been presented in a series of communications to NATURE, was briefly outlined by Dr. Wrinch, who claimed with justice that it is in fact a logical development of the peptide hypothesis built up within the framework of existing knowledge. The criticism of Dr. Linderström-Lang that the cyclol molecule contains linkages of a type not known to be attacked by enzymes was met by Dr. Wrinch with the admission of the possibility of spontaneous breakdown of the structure following initial enzymic rupture of the normal peptide linkages, which it does in fact contain.

The symposium was closed by two brief but interesting contributions, from Dr. Irving Langmuir on the possibilities offered by the study of protein films, and from Dr. D. Jordan Lloyd concerning the important physico-chemical work of Cohn and his collaborators at Harvard.

The general impression left by the symposium was that the problem of protein structure can only be solved by a combination of all applicable methods of attack. The listener was left in no doubt as to the magnitude of the problem, but nevertheless with the feeling that improvements and new developments of technique are now forthcoming at a rate which affords justifiable hope of its solution in the not very distant future.

Health and the Community

ON September 2, the physiologists of the British Association for the nonce forsook their frogs, covies, rabbits and almost, but not quite, their rats. They left the cloistered calm of controlled experiments *in camera* and the discussion of intricate problems of nerve conduction or surface films, interesting, no doubt, to those who have at least mastered the terminology but deadly dull to those who have not, and descended to the world of men, and to a consideration of the criteria of the healthy life both of man as an individual and as an integer in a community. They could not, however, quite part with the rat. The important part this rodent has played and is still playing in the progress of civilization would need a whole article to describe, but we only heard of its value in assaying food for certain vitamins, and were warned of the dangers of accepting results obtained from experiments on rats as applicable without reserve to man. For example, the anti-vitamin D influence of cereals—so clearly demonstrable on rats and puppies, due to the absence from their alimentary tracts of an enzyme capable of freeing phosphate from *phytin*—leads to low-phosphorus rickets, a condition unknown in man. The breakfast cereal, whether provided dry or as Scots porridge, thus leaves the physiological court of appeal without a stain on its character, or, to be more cautious, with the Scots verdict "not proven".

Experiments on animals have given valuable information, and they are still necessary, especially for purposes of assay, but before far-reaching conclusions of value to the community can be drawn, they must be shown to be valid for man by long-term experiments on man. Before these can be attempted, some measure of agreement must be reached as to standards of performance. What is a healthy man? How can his health be measured? It is all very well to talk of the bloom of health, the clear eyes, silky sheen of hair, easy upright carriage and the pleasant facial expression of those physiologically fit, but these qualities are immeasurable. They have no yard-stick. As standards are necessary, such items capable of measurement as height-weight ratio, chest expansion and absence of demonstrable fatigue after moderate work have to be used for want of better. A person may be called normal if he does not depart more than ± 5 per cent from the average.

This led to a discussion on sub-nutrition—a vague lack of efficiency demonstrably due to inadequate intake of the so-called protective foods.

The threshold for these foods varies from individual to individual, some requiring more and some less to enable vital processes to be carried on at full efficiency; so, to play for safety in planning diets for large groups, maximum amounts should be given (not necessarily taken). Laboratory animals have been shown to suffer from excess of these foods. In fact, many diseases common to man may have symptoms similar to those produced by overfeeding rats with certain dietary constituents, but the overfeeding has to be gross. So far, no ill effects have followed *luxus consumption* by a healthy man of any article of diet taken in the ordinary course.

Health and industrial efficiency are not quite synonymous terms, but there is no doubt that ill health causes large industrial losses. The Section had, as guest speaker, Dr. E. Atzler of Dortmund, who told, in fluent English, of his attempts, which met with a large measure of success, to raise the industrial efficiency of the workers in Westphalia. He stressed the value of slow adaptation to working conditions. The operative starting work under new conditions has to become acclimatized, and unless this is done carefully his efficiency and his general health may be impaired. He directed special attention to mineral metabolism—the need for phosphates being noticeable in those about to undergo heavy muscular work, and for chlorides when the work was to be done under semitropical conditions. These mineral needs are less after the worker has become 'hardened' to his job.

The Section turned its attention to more general problems. It was told of a steadily decreasing birth-rate, especially in those classes more financially comfortable. It has been computed that for every hundred women aged twenty-five years in England and Wales to-day, there would be only 83 in 1942, 70 in 1952 and 60 in 1962. Whatever we do now, these figures cannot be increased. Further, there is a tendency to postpone marriage in the better-off classes. Thirty-six per cent of the women of the professional classes who marry do not arrive at the altar until they have passed thirty years of age. The corresponding figure for miners is 10 per cent (Reg. Gen. Report for England and Wales, 1921). Even those who marry younger tend to postpone childbirth. To determine the safest age for reproduction, that is, the age with the lowest death-rate for mother and child, necessitates the close study of a large area with a fairly stable population. Figures were given of 30,000 mothers, 98 per cent of whom came from

the classes covered by State insurance. It was made clear that the safest rate of reproduction for both mother and offspring was the *modal* rate, that is, when the first pregnancy occurred when the mother was round about twenty-five years of age, the second, third and fourth between the ages of twenty-five and thirty and not more than three pregnancies in the next five years. *On the whole*, this rate was observed only by the lower paid members of the community. As income (or security of tenure) improves, there is a tendency to postpone the first pregnancy, with obviously a shortening of the reproductive period and, statistics

showed, with a consequent increase both in maternal mortality and in the number of still-births. The increase in still-births is almost offset by the decrease in child mortality. The result of this is that those who are least able to obtain the necessary food for full health are the very people who are contributing most to the maintenance of the population. To improve the condition of the child-bearers and incidentally of the children born, education in food values and other physiological truths is not of much use unless the necessary food and service are available at a price to suit their incomes and conditions of life. D. B

Obituary Notices

Mr. A. Sharples

MR. ARNOLD SHARPLES, formerly mycologist in the Department of Agriculture, Federated Malay States and head of the Pathological Division of the Rubber Research Institute of Malaya, died at St. Anne's-on-Sea on August 6, after a long illness.

Mr. Sharples was born at Great Harwood, Lancashire, on November 25, 1887. He received his elementary education at Stoneyholm School, Burnley. He left school early, but later, overcoming great difficulties, he became a student at the Burnley Technical College, where in 1908 he won a scholarship to the Royal College of Science, London, and at the same time was awarded King's prizes in both geology and mineralogy. At the Royal College of Science he was especially interested in botany and came under the notice of Sir John Farmer as a particularly promising student. He became an associate of the Royal College of Science and was awarded the diploma of the Imperial College of Science in 1912. His interest in mycology had already been stimulated by his association with north-country naturalists, especially the late Mr. James Needham of Hebden Bridge. On leaving the Royal College of Science he was appointed assistant mycologist in the Department of Agriculture, Federated Malay States, but before going to the East he spent some time at Kew to extend his knowledge of mycology under the direction of the late Mr. G. Massee and Miss Wakefield. All his professional life was spent in Malaya. In 1916 he was appointed chief mycologist in the Department of Agriculture, and in 1930 he was seconded from Government service to be head of the Pathological Division of the Rubber Research Institute of Malaya, situated at Kuala Lumpur. He retired in 1934 and settled at St. Anne's-on-Sea.

During the Great War he served in Mesopotamia (1917-19) as a lieutenant in the Royal Engineers. In this capacity he was concerned with the purification of water supplies for the troops.

From the time of his arrival in Malaya until his retirement, Sharples was a most energetic and able investigator of the diseases of tropical crops, especially rubber. From 1914 onwards there was a constant stream of papers from his pen, published by the Department of Agriculture or the Rubber Research Institute, or appearing at home in the *Annals of Botany* and the *Annals of Applied Biology*. At one time or another he covered the whole range of rubber tree pathology. He treated exhaustively, sometimes in association with colleagues, such diverse topics as the spotting of plantation rubber by mould fungi, pink disease, the root and branch disease of rubber trees caused by *Ustilina zonata*, mouldy rot and brown bast of the tapped bark, lightning damage to coco-nut and rubber trees, and callus formation in tropical plants. These and other investigations were marked by thoroughness and insight. Sharples was not content merely to investigate a disease sufficiently to give advice to planters, but being interested in the fundamental aspects of plant pathology, he examined in great detail the relations of plant and parasite or other disease-producing agency in connexion with environmental conditions. His account (with H. Gunnery) of callus formation in *Hibiscus* and the rubber tree (*Annals of Botany*, 1933) is probably the best description available of the development of this tissue. His wide botanical interests prevented him from becoming a narrow specialist. Sharples was an example of the best type of officer in the tropical departments of agriculture, who realizes both the practical and the fundamental issues involved in problems of crop cultivation.

Sharples had a profound knowledge of all matters concerning rubber cultivation in Malaya, and his advice was constantly sought by the planters, with whom he was always on the best of terms. They had complete confidence in him. He will long be remembered with gratitude by the planting community of Malaya. During his service with the Rubber Research Institute he acted as director for a period.

After retirement, Sharples devoted his leisure to writing an up-to-date book on the "Diseases and Pests of the Rubber Tree" (Macmillan and Co., Ltd., London, 1936). This was a most notable addition to books on the diseases of tropical crop plants; it is, in fact, a treatise on the principles of plant pathology with particular reference to rubber cultivation, and is eloquent testimony to the enlightened outlook which Sharples had on the problems of disease in plants. Unfortunately his health began to fail shortly before the publication of this book, and he died at the early age of forty-nine years. It is sad to think that after such a strenuous life in the East he did not live to enjoy the leisure he had so richly earned.

Personally, Sharples was something of a 'rough diamond', albeit his outspokenness became mellowed with age. He was entirely sincere and courageous in his opinions, and no one was ever a more loyal and kindly friend than he. His high achievement in spite of early handicaps is striking testimony to his sterling character. In an enervating climate he maintained his energy in an astonishing manner: tropical ennui never affected him. In any joint investigation he always pulled his weight, and generously shared credit with his colleagues. As a young man, he was keen on association football and in later life he was fond of tennis and golf. He married Edith Thornton in 1917, who survives him. There were two sons of the marriage, one of whom died a few years ago.

Prof. J. G. Thomson

PROF. JOHN GORDON THOMSON, director of the Department of Medical Protozoology at the London School of Hygiene and Tropical Medicine, whose death took place in London on August 13, was one of the few outstanding medical protozoologists in Great Britain. In addition he was, and continued to be until shortly before his death, a well-known investigator of tropical disease in the field.

Prof. Thomson commenced his career at the University of Edinburgh, where he graduated M.A. in 1903 and where he qualified in medicine with honours in 1908. Two years after qualifying he was appointed Durning-Lawrence research fellow in tropical medicine at Liverpool and later, 1912-13, pathological research fellow at the Liverpool School of Tropical Medicine. During his time at Liverpool, where he worked under Sir Ronald Ross, he carried out many researches on trypanosomiasis and on cultivation of the malaria parasites. His work in this last connexion, which was done largely in collaboration with his brother, Dr. D. Thomson, was perhaps that for which his name was best known.

In 1914 Prof. Thomson was appointed lecturer in protozoology at the London School of Tropical Medicine, but on the outbreak of the Great War he joined the Forces and proceeded in 1915 to Egypt, first as member of a commission to study bilharzia in that country and later as protozoologist to the Central Military Laboratory at Alexandria. On his

return to England he was appointed officer in charge of the Malaria Research Laboratory at the War Office, where again he was associated with Sir Ronald Ross. Whilst in Egypt and later, he published many papers on amoebic dysentery and other intestinal protozoal conditions, as well as studies directed to the finding of satisfactory serological tests for malaria.

In 1918 Prof. Thomson took up the duties of the appointment at the London School of Hygiene and Tropical Medicine which he held at the time of his death; there he worked in post-graduate teaching and in the carrying out of many researches. In 1921 and again in 1922 he went on an expedition to study blackwater fever in Rhodesia. The results of these investigations were presented in a memoir, published by the School, which is now one of the best-known standard accounts of this disease. In 1924 he visited the West Indies, Honduras, Guatemala, Costa Rica and Panama. In 1934 he visited and carried out investigations in Nyasaland, studying more especially the indigenous malaria, and at various times he visited other tropical countries. In the intervals of travelling and demands made on his time by teaching, he published many papers on protozoological subjects and was joint author in Thomson and Robertson's "Text Book of Protozoology", a very useful and condensed source of information on the subjects dealt with.

Though Prof. Thomson worked at many different problems, the malaria parasites were always his favourite study, and even up to shortly before his death the nature of malarial immunity and drug treatment in malaria were much engaging his attention. Prof. Thomson's name is one familiar to research workers in tropical medicine both of British and of other nationalities, and his death will be a loss not only to his colleagues and many friends but also to a very wide circle where his work was known and appreciated.

Prof. Luigi Pernier

WE regret to record the death of Prof. Luigi Pernier, professor of archaeology and the history of ancient art in the University of Florence, which took place in Rhodes at the age of sixty-two years in August last, while he was attending the Dante Alighieri course of "Alta Culture". His death is a great loss to archaeological studies in Italy, more especially in connexion with the investigation of the sites of the early civilizations of the Mediterranean area.

Luigi Pernier was born in Rome on November 23, 1874. On completing his education, he was appointed to the Administration of Antiquities, and took part in the Italian archaeological mission to Crete in 1900, acting as director of the excavations at Festos. In 1909 he was appointed director of the Royal Italian School of Archaeology at Athens and of the "Missioni Italiani in Oriente". While he was head of the School, archaeological explorations were carried out in Crete, Delos, the Sporades and Euboea under his direction. In 1916 he was appointed director of the

Archaeological Museum of Florence and of the Musei Etruschi di Arezzo, when he was responsible for the excavation of Vetulonia, Arezzo, Cortona and Orvieto, investigations of the first importance for our knowledge of the Etruscan civilization. After his appointment as professor of archaeology in the University of Florence in 1922, he also became head of the archaeological mission to Cyrene, where important excavations were carried out under his charge.

We regret to announce the following deaths:

Prof. A. J. Ewart, F.R.S., professor of botany and plant physiology in the University of Melbourne, aged sixty-five years.

Miss A. Lorrain Smith, O.B.E., formerly of the British Museum (Natural History), known for her mycological studies, on September 7, aged eighty-three years.

News and Views

Heavy Nitrogen

At a recent meeting of the American Chemical Society Prof. H. C. Urey reported that he had prepared heavy nitrogen in considerable quantities (see also p. 512). Ordinary nitrogen has long been known to consist of two isotopes of mass numbers 14 and 15, the heavier one being present, however, to only four parts in a thousand. Isotopes of several elements have been already separated in a fairly pure state; of these hydrogen and deuterium are the best known, but other examples are lithium 6 and 7, and neon 20 and 22. The difficulty of the problem solved by Prof. Urey can be appreciated by comparing it with that presented by the neons, where the percentage difference in mass is greater and also the heavier isotope is naturally present to the extent of nearly 10 per cent, instead of the half per cent in the case of nitrogen. It is stated that the heavy isotope is being separated at the rate of a quarter of a litre a day. The separation of pure heavy nitrogen will undoubtedly lead to a great deal of important work in nuclear physics. Nitrogen 15 differs from nitrogen 14 simply in the structure of its nucleus, there being one more neutron present in the heavier type. Ordinary nitrogen has already proved most interesting, since it can be disintegrated in a variety of ways by bombardment with α -particles, neutrons, protons and deuterons. The investigation of the behaviour of heavy nitrogen under the same conditions should lead to valuable conclusions about the effect of the extra neutron in the nucleus. It has also been suggested that heavy nitrogen will be of great service for research in physiological chemistry, since various substances which are important in the body can be made containing some heavy nitrogen instead of ordinary nitrogen, and while their behaviour will be unaltered, these particular molecules can always be identified later by means of the heavy nitrogen atoms.

Mentality of Fish

DR. J. GRAY's evening discourse to the British Association delivered on September 6 at Nottingham shows how closely the reactions of fishes resemble those of man. In the behaviour of man the involuntary machine-like reflex plays a very important part, and in a fish that is swimming freely the movement involves a high degree of co-ordination between a

large number of muscles; the whole of this highly co-ordinated mechanism being completely independent of that part of the fish's brain which corresponds to our cerebral hemisphere and therefore to that part of the brain which is associated with consciousness in ourselves. It is well known, however, that a fish may be trained to make mental associations, and in the last few years the problem has been subjected to rigid scientific investigation. By experiment it is found that a fish is sensitive to a great variety of gentle stimuli such as a very slight change in temperature and the shape and colour of objects in its vicinity. Fish are also capable of carrying out highly complicated migratory excursions. In these types of behaviour Dr. Gray asks us if we do not see most if not all the activities of the human race. Almost certainly the association powers of a fish are on a much lower level than those of man, but the power is there, and it is difficult if not impossible to put our finger on any one of our mental powers and say, "Herein are we a race apart, elevated above the rest of the world". Dealing with the migratory experiments with the Pacific salmon, in which that fish is proved always to return to its own native waters, he says, "I venture to think that if we were to have carried out comparable experiments on a race of human beings, and got similar results, we would have said 'They do it, as you or I would do it, consciously noting the landmarks, memorising them, and so retracing their steps'—in fact they are performing a conscious act, a premeditated, thoughtful, and purposive act. Are we to apply the same conclusions to the fish—if not, why not?"

Rivers and their Formation

IN connexion with the recent British Association meeting at Nottingham, a public lecture on "Rivers", which was abundantly illustrated, was delivered by Mr. R. Kay Gresswell in Lincoln on September 3. Mr. Gresswell pointed out that when a river has once been formed, by virtue of its motion the water is able to carry a load consisting of rock actually dissolved in the water and also of finely powdered rock and pebbles of all sizes, which serve as eroding agents. When it has acquired a load, the river can use it as a kind of file or battering-ram with which to erode its banks and bed and so add to the quantity

it is transporting until it becomes fully laden. The main features of a river are the direct result of the water constantly trying to adjust its bed to suit its load. If the river enters a reach fully laden and the slope is such that the water continues to flow at its original speed, then just as much material will leave that reach as enters it and so no erosion takes place. Should, however, a fully laden river enter a reach the slope of which is less steep than it has been upstream, the rate of flow of the water will be decreased and a proportion of the load is then deposited. This mostly occurs at the beginning of the reach and thus the river gradually steepens the slope until it becomes sufficient for the entering load to be carried through.

In the lower part of its course, a river normally enters upon a plain. Here the rate of flow is greatly diminished and the fully laden river proceeds slowly towards the sea. In turning a corner, the speed on the outside of the curve is always much greater than that on the inside. This results in the water on the outside being able to take on an additional load and thus erode the bank. Conversely, the water on the inside is unable to carry the whole of the load it already possesses and deposits sediment on the inside of the curve. The bend thus becomes steeper and steeper, and it is owing to this action that rivers always meander in the plain tract. Quite commonly the river still does a little actual erosion and in consequence by the continual change of position of the various loops of the meanders, the general level of a strip of land, about one or two miles wide in the case of rivers the size of those found in England, is gradually lowered, the edges of this band, which mark the extreme limit of past meanders, often forming steep cliff-like slopes. If, as the result of earth-movements, the general slope of a river-valley be increased, the river flows more quickly and is thus able to increase its erosion. It sometimes happens that a meandering river is thus rejuvenated, and in that case the river deepens its bed in the shape the meanders then happen to possess. The land between the individual loops are then in time left standing high above the new low river-level. This has happened in the case of the River Wye in Monmouthshire, and has resulted in very beautiful scenery.

Fauna and Climate in Early Palestine

IN view of the interest of the various geographical and distributional problems in the prehistory of Palestine, to which a notable contribution has been made by the preliminary examination of the finds in the bone-bearing beds of Bethlehem (see NATURE, Sept. 4, p. 431) attention may be directed to a communication from Prof. L. Picard, of the Hebrew University, Jerusalem, which appears in the recent issue of the *Proceedings of the Prehistoric Society* (Jan.-June). Prof. Picard there examines in detail the data of palaeontology, geology, archaeology and stratigraphy in their bearing, first on the climate of Palestine in prehistoric times, and secondly on the origin and geographical relations of the fauna of that period.

Writing before the publication of the evidence from Bethlehem, he concurs with Miss Bate's previously published conclusion as to the complete absence from Palestine of a boreal (cold period) fauna, though its existence has been asserted; but he is unable to accept her interpretation of the palaeontological evidence as pointing to a change from a forested landscape with humid conditions to a drier climate and more open country. He finds that while there were a number of forms, now extinct, contemporary with the old Acheulean—the earliest evidence of man's handiwork then available to him—some of these, such as probably the hippopotamus, survived even so late as Biblical times.

As a whole, the various classes of evidence (in palaeontology, trees and plants, as well as land and aquatic fauna) are interpreted by Prof. Picard as concurrently pointing to the fact that no important change in climate takes place down to recent times. In fact, the present climatic conditions, the aridity of the eastern section and the Mediterranean or 'eolian' climate of the western, existed in the Pliocene, and date back to the Upper Miocene. Further, the geographical conditions in the south were such as to preclude migration to, or from, Africa in the Pleistocene. The fauna which has been designated as African-Asiatic has been domiciled in Palestine since the end of the Miocene and can be regarded as endemic during the Plio-Pleistocene. The problem, it will be seen, is of considerable general interest, but to palaeontologist and archaeologist more especially in relation to recent discovery in East Africa. Further evidence from Bethlehem will be awaited eagerly.

Human Skeletal Remains in London

EXCAVATION work in Farringdon Street, London, E.C.4, for the foundations of an extension of the offices of the *Evening Standard* has brought to light a large number of human skeletal remains. About three hundred skulls and two thousand other bones have been found. It is suggested that the excavation may have opened one of the pits in which victims of the great plague of 1665 were buried indiscriminately. There were a number of these pits situated in various parts of London. One of the largest was in Tothill Fields, Westminster, near where Carlton Hall now stands; another near Newgate was adjacent to the site of Christ's Hospital, the Bluecoat School, demolished for the extension of the Post Office, and still another was in Whitechapel. Dr. A. J. E. Cave, of the Royal College of Surgeons, who has inspected the recent finds, is of opinion, according to a statement published in the *Evening Standard* of September 10, that, judging from their condition, they are probably the skeletons of men, women and children who died in the seventeenth century and may well have been victims of the plague. They are all of the same type, and differ but very slightly from typical skulls of to-day. Though they have not yet been submitted to an exact examination, Dr. Cave is stated to have said that the skulls appear to have a

vault a little more pointed than the modern skull. It will be remembered that Prof. F. G. Parsons some years ago examined a large number of seventeenth and eighteenth century skulls of Londoners, when a graveyard, presumably of the adjacent St. Clement Danes, was discovered on the demolition of King's College Hospital in Portugal Street. He then concluded that little change had taken place in the physical characters of the Londoner during the last two or three hundred years, except that the skull showed a slight tendency to broaden.

Recent Excavation at Meare, Somerset

A FORTNIGHT'S work of excavation at Meare Lake Village by Mr. H. St. George Gray and Dr. A. H. Bulleid has brought to light an interesting variant in the method of constructing their dwellings employed by the inhabitants. The season's work, as already indicated (see *NATURE*, Aug. 28, p. 352), is directed to the investigation of the central portion of the eastern half of the village. Excavation of the area surrounding Dwelling Mounds Nos. 16, 17 and 19, which, it is reported in *The Times* of September 13, has now reached the southern half of the floors of the circular dwellings, has shown that there are at least two floors, or layers of clay, separated by a quantity of ash, black earth and refuse deposited during the occupation. The peat in this part of the village is so firm that the usual timber foundations for the support of the clay floors appear to have been unnecessary. In the area surrounding the dwellings the refuse from the huts is found to contain a considerable amount of ornamented pottery (Iron Age "B") and evidence of weaving in the form of loom weights, spindle whorls and bobbins. Portions of bone needles also have been found. In the occupational refuse between the clay floors, the proportion of bones and pottery sherds found to the area at present examined is unusually high. The bones are mostly of lamb and young oxen, but there are also the remains of a small horse, pig and dog, a few bones of red and roe deer and also of birds. Here there is further evidence of weaving—spindle whorls of baked clay, stone and tin, bobbins, etc., as well as a highly polished bone needle and two bone pins with mouldings and long slots of a type unusual in western Britain. Objects of iron are not plentiful, but include a butcher's knife with convex edge. In bronze are a couple of fibulae, an openwork harness ornament, and a hinge-plate with rivet holes. The ornaments include shale bracelets, and among the beads is one of blue, strung on a bronze wire.

Recent Earthquake in Sussex

SHORTLY after 1 a.m. on September 8, an earthquake of intensity 5 or more (according to the Rossi-Forel scale) was felt in the west of Sussex, especially at Horsham and the neighbouring village of Warnham. The earthquake is of some interest owing to its connexion with the series of shocks that have occurred for nearly three centuries in the district around Chichester, the first known to us being that of the year 1553. A little more than a

century ago, between September 1833 and August 1835, there was a series of eight earthquakes in the district, which were studied by a small committee, the first ever instituted for the study of British earthquakes. One of the most important of these earthquakes was that of January 23, 1834. It was of about the same intensity as the recent shock. Its centre lay 4 miles west-north-west of Chichester, and the longer axis of its disturbed area of 780 sq. miles, if produced, passes through Horsham. Readers who are willing to aid in the investigation of the new earthquake should send their accounts to Dr. A. T. Dollar, Emmanuel College, Cambridge.

Mechanization in the Modern World

AMONG the matters handled at the meeting of the International Committee on Intellectual Co-operation at Paris on July 12-17 was the inquiry into mechanization in the modern world. The plan of this inquiry has been approved by the Committee and preparations are now in hand by the Institute. National lists of organizations concerned with social sciences are also being collected by the Institute, and lists have already been received from the United States, France, Japan, Italy, Czechoslovakia, Belgium and Norway. The inquiries on unemployment among intellectual workers are being pursued and the establishment of an advisory committee including representatives of the national bureaux and international organizations concerned has been authorized. The Institute has also collected most of the bilateral intellectual agreements in a volume which will shortly be published. The International Committee on Intellectual Rights has been concerned with preparations for the revision of the Berne Convention and for the Universal Conference on authors' rights, and a meeting of experts is being held to formulate final proposals for two conferences at Brussels on these subjects. The Advisory Committee of Intellectual Workers of the International Labour Office, however, pronounced in favour of keeping the question of the moral rights of salaried artists in the applied arts on its agenda.

The S.S. *Orcades*; the Latest Orient Liner

LAST month the Orient liner *Orcades* started on her maiden voyage. According to an article in the *Electrical Review* of August 27, it is claimed that she is the first British ship on the Suez route to have a public sitting-room supplied with conditioned air. Conditioned air is supplied to the public rooms and to several of the cabins. It is not sufficient for comfort to have only ventilation and correct temperature; the humidity must also be controlled within fairly narrow limits. In the tropics, the atmosphere is frequently uncomfortably damp. To reduce the temperature without extracting moisture from the air raises the relative humidity and may make the conditions more uncomfortable. When the climate is colder, air after warming sometimes becomes unpleasantly dry. Hence although air conditioning as it is managed at present is expensive, it may add greatly to the comfort and well-being of the passengers. The new vessel—an eight decker—has been built by

Vickers Armstrong for cruises and for service on routes between England and Australia. Its gross tonnage is 23,445 and it will accommodate 463 first-class and 605 tourist passengers and a crew of 466. Steam is provided by six oil-fired Babcock and Wilcox boilers. Pipes conduct it to two sets of 1,715 revs. per min. Parsons turbines. These drive the propellers at 112 r.p.m. by means of mechanical gearing. Two systems of intercommunication telephones are installed. The Marconi International Communication Co. has installed an all-wave radio installation, including a direction finder, and an 'echometer' depth sounder, together with a broadcast system of loud speakers throughout the vessel. Time is given by means of 82 synchronous clocks. A portable sound picture equipment by the Western Electric Co. is one of the many forms of entertainment provided.

The Problem of Dates of Publication

THE study of natural history has branched into many side-lines; but it is strange to think how far off the direct line of acquisition of nature knowledge the need for accuracy has led. For the convenience of naturalists the world over, animals and plants bear specific names, and the proper name where several have been given is determined conventionally by priority of christening. But so difficult is it in some cases to determine priority that an extensive literature has developed around these knotty problems, and so insistent is the demand for accuracy that a Society for the Bibliography of Natural History has been formed. The first part of its *Journal* is a catalogue of papers concerning the dates of publication of natural history books, arranged in alphabetical order of the authors of the books, and this ought to be of great service to systematists. Sometimes it is difficult to see exactly how the alphabetical order has been determined; "Ent. Soc. Lond." appears under "London", "Ent. Soc. N. S. Wales" under "Ent."; "Royal Phys. Soc. Edinburgh" appears under "Proc.", while the Wernerian Society of the same city appears under "Edinburgh". Doubtless there are sound reasons for this grouping, but they are not obvious, and they are not set out in the very brief introductory notes. The Society maintains a card index of papers concerned with the dates of publication of natural history books, and copies of such papers will be welcomed by the Secretary at 41 Queen's Gate, London, S.W.7.

Empire Grants Committee for Museums

THE final report to the Carnegie Corporation of New York on the activities of the Empire Grants Committee appears in the *Museum Journal* of May. It is a stimulating document. On April 1, 1934, the Committee was set up to administer a fund of 54,000 dollars granted by the Carnegie Corporation of New York for Colonial Museums, with an addition of 9,000 dollars for expenses, £12,560 in all. All museums in the British Colonies, and in Newfoundland and Southern Rhodesia were invited to submit applica-

tions for grants; forty applications were received and twenty-five grants were made. They ranged from £80 to Kandy Museum and Bermuda Historical Museum to £1,000 for Nairobi, Cyprus, Barbados, Singapore, Zanzibar, Jamaica. Various strict regulations had to be made as to the conditions upon which grants could be made; but the Committee is satisfied that the effect of grants has been in nearly every instance most stimulating to the local museum movement. At Bulawayo and Salisbury, the museums have been elevated to the dignity of national museums; in Cyprus, Barbados and Antigua more attractive premises and added Government recognition have been gained; but in most cases grants have been given for cases and equipment, so that museum interiors have been brightened and organized on modern lines. The success of the experiment leads the Committee to suggest that there are good reasons for continuing so promising a first effort.

Time Measurement

THE history and development of time measurement have already been described in a Science Museum Handbook ("Time Measurement", Part 1). The second part of the handbook which has recently been issued (London: H.M. Stationery Office. 2s. net) contains a detailed description of the objects in "The Time Measurement Collection at the Science Museum, South Kensington". The exhibits, ranging from the ancient Egyptian shadow clocks and water clocks to modern electric time-keepers, include sundials, mechanical clocks, watches and chronometers, escapement models and chronographs, as well as various auxiliary devices such as striking mechanisms, time recorders and time switches. Introductory remarks to each chapter explain the system of classification adopted, and outline the general principles involved in the respective groups of instruments. Many of the exhibits at the Science Museum are shown in continuous operation, while others can be operated by visitors—a facility that appears to receive perpetual appreciation. In addition, several of the more delicate watch mechanisms are illustrated by large-scale models. It may be noted that Harrison's four marine timekeepers (the fourth, completed in 1759, being the chronometer which won for Harrison the British Government prize of £20,000) are now represented in the Museum only by photographs, the originals themselves, long associated with the Royal Observatory, Greenwich, having been transferred to the National Maritime Museum at Greenwich. This handbook with its numerous illustrations provides an admirable introduction to a study of the Time Measurement Collection, and it will also serve as a useful handbook of reference for other occasions.

Meteorology in India

THE Meteorological Department of the Government of India has for several years had to contend with serious financial obstacles in the shape of reduced grants, when the increasing requirements of aviation have demanded increased departmental activity. The

report on the Administration of the Meteorological Department of the Government of India in 1935-36 (Delhi: Manager of Publications, 1936) describes how various economies have been devised in order that the demands of aviation and other interests may be met so far as is possible. By taking full advantage of aeronautical wireless stations for the exchange of weather telegrams between aerodromes, and aided by cheaper telegrams, a saving of more than half a lakh of rupees annually has resulted. Economy was not made any easier by the disastrous earthquake of May 31, 1935, at Quetta, which demolished the Meteorological Office there, as well as the observers' quarters. This led to the pilot balloon station at Quetta being moved to Dera Ismail Khan for a time, and to the setting up of a temporary surface observatory at Quetta when the situation there was well enough in hand again. Research work did not slacken. Dr. T. Royds, director of the Kodaikanal Observatory, joined the expedition organised by the Royal Society and the Royal Astronomical Society to observe the solar eclipse of June 19, 1936. He took with him what is described as "perhaps the most powerful spectrograph ever used at an eclipse". The discovery of oxygen in the sun's chromosphere was announced from Kodaikanal in 1936 (see NATURE of April 11, 1936). Several pieces of research were carried out in the office at Poona with the voluntary aid of students guided by the official meteorologists. These included the development of a spectrograph for the study of ozone in the earth's atmosphere.

Activities of the Rockefeller Foundation

A REVIEW by its president, Mr. Raymond Fosdick, surveys the work of the Rockefeller Foundation during 1936. The expenditure totalled 11,300,000 dollars in connexion with its programme "to promote the well-being of mankind throughout the world". The agencies assisted included institutions, research work in medicine, biology and other sciences, and the humanities. Investigations on the jungle form of yellow fever and other health problems have been promoted, displaced German scholars have been helped, and appropriations have been made for trial work in the development of radio-programmes of cultural and educational value. A grant was given to the Orthological Institute in China for the preparation of a series of books for Chinese readers in 'basic' English.

Encke's Comet

A TELEGRAM from Copenhagen announces that Dr. Jeffers, Lick Observatory, has observed Encke's Comet. The position on Sept. 3-38542^d U.T. was R.A. 2^h 19^m 4.9^s, N. Decl. 27° 10' 20". The magnitude is given as 18. In the "Handbook of the British Astronomical Association" for 1937, Dr. A. C. D. Crommelin gives an ephemeris based on an orbit in which perturbations of Jupiter and Saturn are taken into account. The observed position corresponds closely with that predicted by Dr. Crommelin.

Discovery of a Super-Nova in *Canes Venatici*

PROF. H. SHAPLEY has announced the discovery of a super-nova by Zwicky, and Humason found that it had a typical super-nova spectrum. Stobbe, at Kiel, gives its position as R.A. 13^h 2^m 57.56^s, N. Decl. 37° 57' 19.2", equinox 1937.0, and magnitude 8.7.

Announcements

A DEPARTMENT for psychology under the direction of Prof. E. R. Jaensch, director of the Institute of Psychological Anthropology at Marburg, has recently been added to the Imperial Leopoldine Caroline German Academy of Natural Science.

THE following awards have been announced by the North East Coast Institution of Engineers and Shipbuilders: The Institution Engineering Gold Medal to Harry Hunter, vice-president of the Institution, for a paper on "Singing Propellers"; M. C. James Medal to Mr. H. E. Lance Martin, head of the Civil Engineering Department at King's College (formerly Armstrong College), Newcastle-upon-Tyne, for a paper on "The Determination of the Residual Strains and Stresses in Arc-Welded Plates"; The Institution Scholarship, value £100, to R. A. Lyall, an apprentice of the Central Marine Engine Works, West Hartlepool.

THE board of Rolls-Royce, Ltd., has decided to found, in memory of Sir Henry Royce, a travelling research fellowship to be known as the Henry Royce fellowship. The Fellowship will not exceed £450 a year and will be tenable for one year, by a graduate of a British university or holder of the higher national certificate or other equivalent qualification. Research is to be concerned with the construction, design, materials, or methods of production of automobile transport, including applications to aircraft and modern engineering.

AN International Conference on Physics, Chemistry and Biology will be held in connexion with the Paris International Exhibition in the Palace of Discovery on September 30-October 9. The president will be Prof. Jean Perrin. Further information can be obtained from the General Secretary, L. W. Tomarkin, 11 Rue Pierre Curie, Paris, 5^e.

THE ninth Annual Conference of the National Smoke Abatement Society will be held at the Philosophical Hall, Leeds, on September 30-October 2. The programme includes discussions on town planning and smoke abatement, and education and smoke abatement. Further information can be obtained from the Secretary, Chandos House, 64 Buckingham Gate, London, S.W.1.

DURING the forthcoming winter, Mr. H. V. Garner, the guide demonstrator of Rothamsted Experimental Station, Harpenden, Herts, and other members of the staff are available for giving lectures to interested institutions on the Rothamsted experiments. All communications regarding lectures should be addressed to the Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 509.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Observations of the Solar Eclipse of June 8, 1937

A SCIENTIFIC expedition was organized early in the present year to observe the total solar eclipse of June 8 from somewhere on the coast of Peru, and the party of three sailed from Yokohama in the beginning of April. I was in charge, and arrived at Lima on May 10; after consultations with the Eclipse Committee of the University Mayor of San Marcos, I decided to have the observing station at Hnanchao, some 14 kilometres north-west of Trujillo. Two other members of the party, together with the instruments, landed at the port of Salaverry on May 20, and immediately proceeded to the station.

A large house of Sr. Victor Larco Herrera was kindly put at our disposal, where a large party of Peruvian scientific workers under Dr. G. Garcia was staying for the same purpose. Early in June, Dr. Clyde Fisher's American party also came to the same spot.

The main object of our party was to take large photographs of the inner corona with a ten-metre camera in conjunction with the 30-cm. ocularstat. Further, I had an independent set of cinematographic arrangements to get a rapid succession of photographs of three visible contacts, spectra of the flash and the corona, the extensions and the brightness of the corona. As the sun was about $9\frac{1}{2}^\circ$ in altitude at the time of the eclipse, all instruments were set conveniently inside the rooms of the house and the sun could be observed through the available windows. A separate room was used for meridian observations of longitude and latitude made by me with a 38 mm. astronomical theodolite, the roof being taken away temporarily.

The weather was generally good during the interval of our stay at the camp, except for a few days in the very beginning of June when the skies were continuously overcast. The rehearsals and other preparatory work were well carried out.

On the day of the eclipse, the sky was overcast in the morning, but later it became clear and by 3 o'clock we had a perfect sky. The three visible contacts were observed as follows:

	1st Contact	2nd Contact	3rd Contact
Observed standard time	16 ^h 15 ^m 20 ^s	17 ^h 18 ^m 20 ^s	17 ^h 20 ^m 57 ^s
Corrections to computed time	+6	+3	+5
Observer	M. Horii	I. Yamamoto	I. Yamamoto

With the ten-metre camera, four plates were exposed for the partial phase and eight for the totality, with the exposures ranging from one tenth to 30 seconds. Upon developing, these plates have revealed splendid structures of the inner corona. My own cinematographic arrangements were partially successful, revealing good images only of the inner corona and the flash spectra.

According to these photographs, the coronal streamers are well developed around the sun. Especially in the north-east portion of the sun's limb there is a group of strong streamers and arches over

a wide area, where daily observations of the sun's surface during previous weeks suggest an activity area of large sunspots. Characteristic rays from both the north and the south poles of the sun are completely hidden by strong coronal streamers. Hence the present corona is of the 'sunspot maximum' type.

There are about a dozen prominences visible around the sun. Two of them are magnificent, one in position angle 35° and the other in 290° .

I observed the longitude and latitude of our station on three nights. The preliminary result for the latitude is $-8^\circ 4' 46.6''$, but that of the longitude has not yet been reduced.

Photo-conductivity and Phosphorescence of Zinc-blende

FROM early experiments on the photo-conductivity of zinc-blende, Gudden and Pohl¹ deduced that the current must be transported by two kinds of carrier, and according to present-day theory these must be electrons and 'positive holes'—vacant places left in a normally full electron energy band when an electron is ejected. While electrons are liberated by blue light, positive holes do not become mobile until a subsequent illumination by light of longer wavelength, for example red or infra-red, but the reason for this need not be discussed here.

The photo-induced conductivity is proportional to the intensity of illumination, which shows that electrons travel a finite distance (*Schubweg*) and are then 'trapped', the trapping *not* being in general due to recombination; for if it were, the current would be proportional to the square root of the illumination. The mechanism of this trapping need not concern us here; but either under infra-red illumination or thermal agitation the trapped electrons can be set free again. Trapping and re-liberation occur a number of times in succession, but the electrons finally come to rest by combining with a positive hole. The crystal is then said to be quenched.

That this is the case is shown by the way in which the conductivity dies away during quenching. If n is the number of electrons (a constant proportion of which will be in the conducting state), and also the number of holes, then if they are recombining their number will decrease according to

$$\frac{dn}{dt} = -c_1 n^2,$$

whence, integrating, we obtain

$$\frac{1}{n} = c_2 t + c_3,$$

c_1 and c_2 being constants. Thus we shall expect the

resistance of the crystal to be a linear function of the time. This is confirmed by experiment. For example, Fig. 1 shows the resistance-time relation found during the quenching of a specimen by infra-red light at -196°C . It is seen that within the limits of experimental uncertainty the relation is linear.

It is interesting to note that phosphorescence decay data for zinc-blende obtained recently by Antonow-

Fig. 1.

Romanowsky² are in full accord with these results, in that they show that the phosphorescence is due to a bimolecular reaction. It is easily seen that on the assumption that the intensity of phosphorescence, p , is proportional to the rate of recombination of electrons with holes, $p^{-1/2}$ should vary linearly with time. Plots of $p^{-1/2}$ against t , obtained from Antonow-Romanowsky's data, show that this is,

Fig. 2.

indeed, the case. An example of such a plot is given in Fig. 2, in which the lower line is to be regarded as a continuation of the upper one, representing the points on the two reduced scales.

Phosphine and Arsenic Derivatives of the Group I(b) Metals: Volatile Derivatives of Gold

WE have shown that the trialkyl phosphine and arsenic derivatives of cuprous iodide, previously considered to be $R_3P(As) \cdot CuI$, have a fourfold macro-molecule¹, $[R_3P(As) \rightarrow CuI]_4$, and are therefore tetra-kis-[iodo-trialkylphosphine (or arsenic)-copper]. A complete X-ray examination of the triethyl-arsine member, $[Et_3As \rightarrow CuI]_4$, showed that the four copper atoms occupy the apices of a regular tetrahedron; the iodine atoms are situated each above the central point of one face of this tetrahedron, so that they also form a tetrahedron external to that of the copper atoms. Beyond each copper atom is an arsenic atom lying on the elongation of the axis joining the centre of the inner tetrahedron to the copper atom. The iodine atoms are thus 3-covalent, each being joined to the three neighbouring copper atoms apparently by one covalent and two co-ordinate links: if this is so, the stereochemistry of the 3-covalent iodine atom must be similar to that of 3-covalent sulphur, and the iodine atom can be regarded as occupying one apex of a tetrahedron with its valencies directed towards the other three apices.

The corresponding silver compounds have now been examined, and prove also to have the fourfold molecule, $[R_3P(As) \rightarrow AgI]_4$. These silver compounds have, moreover, the same constitution as the cuprous compounds, since $[nPr_3As \rightarrow AgI]_4$ is strictly isomorphous with $[Et_3As \rightarrow CuI]_4$. This is a remarkable example of isomorphism, the effect of the replacement of the copper by silver atoms being compensated by the replacement of the ethyl by the *n*-propyl groups. It follows that both the 4-covalent cuprous and argentous atoms have a tetrahedral configuration, in confirmation of the results obtained by Cox, Wardlaw and Webster².

The aurous compounds, $[R_3P(As) \rightarrow AuX]_4$, where X is a chloride, iodide or thiocyanate radical, prove, however, to be monomolecular, and the gold thus shows a true co-ordination number of 2. The phosphine compounds, $[R_3P \rightarrow AuX]_2$, where X is Cl or I, possess remarkable stability, and can be freely distilled under reduced pressure. The compound $[nBu_3P \rightarrow AuCl]_2$ can be volatilized even at atmospheric pressure, and the vapour, if passed through a heated tube, deposits a fine film of gold. There are thus two distinct chemical methods of producing gold films, the first having been recently described by Prof. O. S. Gibson in NATURE of August 14 (p. 279).

It is noteworthy that, whilst the copper and silver atoms both acquire 7 electrons in the above compounds and thus attain the electronic structure of the next inert gas, the gold atoms acquire only 3 electrons and thus remain 4 short of the radon structure. The gold in these compounds, however, falls in line with mercury, which acquires 2 electrons in compounds such as HgR_2 and $Hg(SR)_2$, and with thallium, which acquires 1 electron in compounds such as $[TlR_2]X$, a group of 4 shared electrons in the sixth quantum group allowing considerable stability in all three cases.

Behaviour of Cylinders of Inflammable Gas in a Fire : Extinguishing Flames by Coal Gas

On the night of October 5, 1936, a fire occurred in Pearse Street, Dublin, in a shop which housed two full cylinders of compressed gas, one containing 150 cu. ft. of oxygen, the other 100 cu. ft. of coal gas. In each case the internal pressure was 120 atm. During the fire explosions took place, and a large portion of the building collapsed. It was found afterwards that three firemen had lost their lives. A Tribunal of Inquiry, appointed by the Minister for Local Government and Public Health of Saorstát Éireann, has recently issued its report (Stationery Office, Dublin). "The Tribunal is satisfied that the explosions must be attributed to the two full cylinders of coal gas and oxygen," and includes among the results of the explosions "the trapping of three firemen who were then within the building thereby causing their deaths".

The fire, and the inquiry which followed, raise a point of general interest. If a fire occurs in premises in which cylinders of compressed gas are stored, will that fire be likely to be much more disastrous than if cylinders are absent?

In the present instance, there is no doubt that the cylinders burst in the course of the fire, for they were found ruptured in the ruins. There was general agreement, however, that the result of the physical bursting of a cylinder of compressed coal gas, followed by the burning of its contents, was likely to be much less disastrous than if the contents of the cylinder became mixed with air and suffered chemical explosion.

The men of science who attended the inquiry as expert witnesses found themselves faced with the following problem. Suppose the back of the shop (where the coal gas cylinder was placed) in flames, and suppose the front of the shop not yet on fire. The coal gas cylinder bursts, presumably in the midst of the flames. Could the gas (if the burst took place on the suitable side of the cylinder) make its way through the flames into the air in the front part of the shop, form an explosive mixture, and explode if a flame reached the mixture before it had become too dilute?

There is no doubt that the emerging coal gas could extinguish the flames in immediate contact with the cylinder. Intense cooling (in this instance 500°–600° C.) would result from an almost adiabatic expansion. Further, the concentration of combustible material would far exceed the upper critical explosion limit, which is about 28 per cent of combustible in the case of Dublin coal gas. I expressed the opinion that the jet of coal gas, shot with high velocity from the ruptured cylinder, might thus extinguish the flames in its path, and blast its way through the surrounding fire to the air in the front of the shop, where chemical explosion would probably follow. The alternative picture submitted was that of the coal gas swelling out of the ruptured cylinder as a 'balloon' which would necessarily be kindled at its periphery. It would then make its way to the nearest outlet as a gigantic flame, prevented by a mantle of burnt gases from mingling with air so as to form an explosive mixture.

The essential problem is therefore: Can a jet of coal gas extinguish flame *without itself being ignited*? If the answer is in the affirmative, there exists a possibility of chemical explosion in a case such as the present. Whether explosion actually occurs will depend on a variety of factors, such as the volume

and pressure of the escaping combustible gas, and the extent of the fire by which the container is surrounded.

I have carried out experiments, which I believe to be new, showing that coal gas *can* extinguish flame without itself being ignited.

A coal gas flame, five or six inches high, was established in the open air. A small cylinder of compressed coal gas (20 cu. ft.), fitted with the usual nozzle to control the rate of discharge, was used. The nozzle was opened full and the stream directed, from a distance of 3–4 ft., on to the flame. After a little practice, one was able to extinguish the flame without igniting the stream of gas from the cylinder.

A less striking experiment was carried out as follows. A five-litre flask was filled with coal gas, and the mouth covered with thin paper to form a temporary barrier to the gas. The flask was adjusted, mouth downward. A small gas flame was prepared. The tube from which this gas issued was surrounded at the mouth by a short piece of wider glass tubing with irregular edges, to puncture the paper before the flame reached it. The edge of the wider tubing was only just above the level of the top of the flame. When the flame was pushed up into the flask of gas, it was of course extinguished. The gas which issued from the flask sometimes took fire, but on numerous occasions the flame was extinguished without igniting the gas.

Formation and Breakdown of Amino-acids by Inter- molecular Transfer of the Amino Group

We have previously reported¹ the discovery in muscle of a highly active metabolic mechanism, by the action of which the amino group and two hydrogen atoms of glutamic acid are transferred to pyruvic acid (added or of metabolic origin) with the formation of alanine (and ketoglutaric acid). This is the key to the puzzling fact that glutamic acid is transformed into succinic acid by muscle tissue without the formation of either ammonia or amide nitrogen (D. Moyle-Needham).

Further work, to be published in detail elsewhere, showed this reaction to be a reversible one. From alanine and α -ketoglutaric acid muscle tissue rapidly forms glutamic and pyruvic acids, equilibrium mixtures of similar composition resulting in both the direct and the reversed reaction.

The presence of the enzyme system responsible for this process of *Umaminierung* can be readily demonstrated not only in muscle, but likewise in other organs (heart, brain, liver, kidney), irrespective of their capacity or inability to metabolize amino-acids by oxidative deamination or reductive amination respectively. In organs containing Krebs's aminodehydrogenase the intermolecular transfer of the amino group competes with oxidative deamination and, owing to its greater velocity, completely inhibits the latter process in the presence of an excess of pyruvic acid. Only with nucleated erythrocytes and malignant tissues no evidence of *Umaminierung* has been obtained up to the present.

α -Ketoacids other than pyruvic, for example, α -keto-butyric, α -ketocaproic, oxaloacetic or phenylpyruvic acid, may equally serve as acceptors for the amino group of glutamic acid. On the other hand, all

α -amino acids readily give up their amino groups to α -ketoglutaric acid in the presence of muscle tissue; the formation of glutamic acid has been demonstrated with sixteen different natural and racemic amino-acids including such as glycine or histidine, known to be difficultly accessible to oxidative deamination by surviving tissues. The rate of *Uminierung* is astonishingly high; thus, no less than 6.5 mgm. glutamic acid is formed in two minutes from glycine and ketoglutaric acid by one gram of muscle tissue. This would correspond to a value of $Q_{Uminierung} = 152$. In our opinion, the mechanism of this biocatalytic reaction is the same as that discussed by Herbst¹ in recent studies on a somewhat similar model reaction, occurring when amino-acids are heated with ketoacids in aqueous solution.

Aspartic acid behaves in the same way as glutamic acid (Kariagina, this laboratory), and oxaloacetic acid—as ketoglutaric acid, in the function of amino nitrogen donors or acceptors respectively. The 'trapping' of oxaloacetic acid by the acceptance of amino groups, interfering with the action of Szent-Györgyi's "fumarate system", offers an adequate explanation for the inhibitory effect of amino-acids on the respiration of muscle and other non-deaminizing tissues, repeatedly observed by different authors. An attractive hypothesis on the origin of diabetic ketosis was recently put forward by Koranyi and Szent-Györgyi², who consider this condition as a result of damage to the fumarate system, possibly brought about by *Uminierung* or a similar mechanism.

It deserves special attention that no transfer of the amino group occurs unless either the amino-acid or the ketoacid is a dicarboxylic one. No instance of a direct amino nitrogen transfer between two monocarboxylic acids has yet been observed, but some evidence has been obtained showing that the reaction can be brought about by the catalytic action of dicarboxylic amino- or ketoacids, added in small amounts and functioning as intermediary amino nitrogen carriers. The above data indicate that the dicarboxylic amino- and ketoacids probably play an important and specific part in the intermediary nitrogenous metabolism, bearing some analogy to the catalytic function of the C_4 -dicarboxylic acids in tissue respiration.

Meteorites: the Number of Pultusk Stones, and the Spelling of "Widmanstätten Figures"

(1) IN NATURE of July 17, Dr. Stenz¹ expresses the opinion that not more than 3000 stones fell near Pultusk in the famous meteorite shower of January 30, 1868, and that only a curious misreading of a chemical analysis led to the usually quoted number of 100,000 stones.

The Pultusk fall is of special interest, being one of the very few—six or seven—cases in which the orbit of a meteorite could be calculated; according

to the astronomer Galle², for the Pultusk stones a hyperbolic velocity, hence an extrasolar origin, is proved. Furthermore, from the acoustic and optical phenomena of the fall he concluded that the stones were not fragments produced by an "explosion" in the atmosphere, but had already entered the solar system as a shower. The question as to their approximate number is, therefore, of some importance, and it may be permissible to quote a few statements from the literature which seem clearly to contradict Dr. Stenz's drastic reduction of the figure.

The well-known Bonn mineral dealer, Dr. A. Krantz, procured 34 kgm. of the stones³. He ascertained that 1 kgm. contained some 210 stones with a perfect crust⁴, this being proof that all the stones he counted had fallen as separate units, although some did not weigh more than a gram. It follows that this one dealer possessed more than 7000 stones, that is, more than twice the number Dr. Stenz ascribes to the whole fall. Altogether 200 kgm. were secured⁵, representing—on the basis of Dr. Krantz's statistics—some 42,000 stones. In the shower the smaller stones were obviously more numerous than one would infer from some collections, for which the bigger ones were preferred; but, for example, Dr. Melion's description of the 125 Pultusk stones in his possession⁶, of a total weight of 1150 gm., shows still the marked preponderance of the small type (86 stones of less than 7 gm.).

Now, considering that in the shower the majority only weighed a few grams—the so-called "Pultusk peas"—and that the fall covered an area⁷ of 17 km. $\times$ 6 km. of rough and partially flooded land⁸, the assumption that the total number was two or three times the number of stones recovered is very conservative. Vom Rath⁴ even thinks it possible that several hundred thousand stones fell. There is certainly no reason to change the usually quoted round figure of a hundred thousand for the 3000 of Dr. Stenz.

One gram was apparently the smallest mass anyone in the Pultusk area called a "stone" and thought worth picking up, but Galle² may be right in assuming in the original shower the presence of "innumerable" smaller particles.

(2) For more than a century the well-known etching-patterns on iron meteorites have been called "Widmanstätten figures", after their discoverer, Alois von Widmanstätten (1754–1849). He, however, personally published nothing on the subject, but left this duty to his friends. Four years ago, Dr. Spencer⁹, in a very thorough survey of meteorite literature, showed that the spelling of the name Widmanstätten was not constant, the "tt" sometimes being replaced by "dt", the "a" by "e", and so on, and stated that all the various forms hitherto used are wrong, the correct spelling of the family name being Widmanstetter. Following Dr. Spencer, writers on meteorites in Great Britain and abroad¹⁰ begin to speak of "Widmanstetter figures".

It is certainly no use trying to decide whether "tt" or "dt", "d" or "e" is the more correct spelling of an Austrian name of a hundred years ago; as these differences are not audible in pronunciation, both ways of writing were then considered as equivalent. The "t" instead of "n" at the end of the name is a somewhat more serious difference. A study of the history of this particular family shows that for decades both forms occurred; but Cohen, who was already aware of this discrepancy, on the authority

of Wurbach's dictionary¹⁰, declares in his "Meteoritenkunde"¹¹ that the discoverer of the etching-figures himself usually wrote "Widmanstätten" and therefore this form ought to be chosen. In view of Dr. Spencer's publication, I asked friends in Vienna and Graz to inquire anew about the form of the name personally used by the scientist. They went rather fully into the question and completely confirmed Wurbach's and Cohen's statement. Official documents are still preserved which mention Alois von Widmanstätten as the owner of a house in Graz, as the inventor of a balance, etc.

Keepers of meteorite collections may be glad to learn that there is, therefore, no reason to alter the hundreds of labels bearing the name Widmanstätten.

Response of the Pigeon Crop Gland to Prolactin: Inhibition by Oestradiol Monobenzoate

Riddle and Braucher¹ showed that injections of the hypophyseal lactogenic hormone, prolactin, discovered by Stricker and Grueter², will cause growth of the crop glands of the pigeon. In view of the fact that established lactation is inhibited by administration of oestrogenic hormones^{3,4,5}, it is of considerable interest to determine whether or not simultaneous administration of oestrogens will affect the response of the pigeon crop to prolactin injections.

Two groups of 24 young pigeons of 'homer' type were used. Each bird was given six daily subcutaneous injections of 1 ml. of a solution containing 5 mgm. of prolactin. For the gift of this material, which was prepared by the method of Bates and Riddle⁶, omitting the final purification, we are indebted to Dr. F. G. Young. In addition, on the fifth day before the commencement of the prolactin injections one group was given injections of 1 ml. progynon B oleosum forte (kindly supplied by Dr. H. Neumann of Messrs. Schering, Ltd.) containing the equivalent of 5 mgm. oestradiol monobenzoate in sesame oil, followed by similar injections on the day of commencement of prolactin treatment. The other (control) group received equivalent injections of sesame oil alone. Twenty-four hours after the last injection the birds were killed and weighed. The sex of each was determined and the crop glands dissected out, fixed in Bouin's fluid and weighed from 70 per cent alcohol after pressing in muslin. The mean weights of the crops in mgm. per 100 gm. of body weight at killing are given in the accompanying table, the results for the two sexes being given separately. The crop gland region in the normal

pigeon usually weighs about 300 mgm. per 100 gm. body weight.

	Male		Female	
	No. of birds	Mean crop weight in mgm. per 100 gm. body weight	No. of birds	Mean crop weight in mgm. per 100 gm. body weight
Oestradiol monobenzoate	9	680 (±67)	15	830 (±50)
Sesame oil	7	1490 (±103)	17	1080 (±47)

The figures given in parentheses are probable errors of the means against which they are entered.

In both sexes administration of oestradiol monobenzoate caused a marked inhibition of the crop gland response, the mean inhibition amounting to about 54 per cent in the males ($P = 1:2,500$)* and about 23 per cent in the females ($P =$ about $1:40$).

This difference between the sexes in the degree of inhibition (sex-difference statistically significant at $P = 1:140$) is for the most part accounted for by the fact that in this experiment the reaction of the control birds to prolactin + sesame oil was significantly greater in males than in females ($P = 1:180$), while in the group receiving oestradiol monobenzoate the difference between the responses of the two sexes was negligible.

It is noteworthy that the group receiving oestradiol monobenzoate lost on the average 7.7 per cent of body weight in the course of the experiment ($P = 1:90$), although the control group gained on the average 6.7 per cent ($P = 1:210$). In both groups the mean change in body weight was somewhat greater in the females than in the males.

Since the prolactin response of hypophysectomized pigeons appears to be either nil⁷ or considerably less than that of intact birds⁸ it is possible that oestradiol monobenzoate inhibits the response by way of the pituitary.

Some Interrelations between Bivalve Spatfalls, Hydrography and Fisheries

IN a study of the intensity and distribution of spatfalls of *Cardium edule* on the Cork sands in Morecambe Bay, it was found that the heaviest falls occur (a) where tidal streams meet—such localities being described locally as 'meetings'—and (b) where banks shelter a stretch of ground from prevailing winds. The heaviest falls occur at about the half-tide level.

The fall of spat is contemporaneous with considerable depositions of fine sand intermingled with some

detritus, and larvæ and post-larvæ of various other organisms such as *Polydora*, *Macoma*, other bivalves and worms. Such settlements form a densely populated mud or slutch. The same phenomenon occurs in the Dee estuary. In winter the slutch disappears.

It is clear that the *Cardium* and other organisms become concentrated and precipitate out of the plankton in localities where slack and eddy waters occur. As many as 100,000 young *Cardium* per square metre may occur in the centre of such areas¹, with diminishing concentrations towards the periphery of the meetings and low values outside them.

Recognition of these conditions at once suggested comparison with those found by Davies² on and near the Dogger Bank. Here concentrations of the fish-food, *Spisula truncata*, up to 8,250 per square metre occurred in the centre of elongated or ovoid areas, with diminishing numbers to the periphery in each case. This distribution resembles that of *Cardium* and other organisms in Morecambe Bay, and it was suspected might be brought about in a similar way, namely, by the concentration of the planktonic forms in eddying waters over and around the Dogger Bank. Recently Tait³, in investigating the surface drift of water in the North Sea, finds stream currents giving rise to eddies or swirls in several localities, including one on the north-east of the Dogger Bank. This eddy practically overlies the part of the Dogger Bank where Davies found the great spatfalls of *Spisula*.

There can be little doubt that immense quantities of larval fish foods in the form of bivalves and worms become concentrated in these swirls or eddies. Where sub-surface conditions are suitable as over the Dogger Bank, in the Moray Firth, in the mid-east Scottish coast and other areas, the larvæ settle out of the plankton to form rich feeding grounds for fish. We have therefore now a rational explanation of how such grounds are formed, and a clear indication of where to find them. On natural oyster beds oyster larvæ also tend to settle most frequently (a) where eddies form, as at the junction of a side stream with the main one, as well as in eddies formed along the shores of the main channel, and (b) in other regions of relatively still water⁴.

In the recent planktonic studies in the south-western North Sea by Savage and Hardy⁵ and Savage and Wimpenny⁶, only the area of the drift west and south-west of the Dogger Bank was investigated, and it is a reasonably safe prediction that an immensely rich planktonic area remains to be discovered in the eddy over the north-eastern region of the Dogger Bank. This eddy is not stationary, so that spatfalls may settle out in different but adjacent places, as is apparent from Davies's justifiably painstaking research. These spatfalls indicate, moreover, that the eddy over the Dogger Bank may extend sometimes from the surface into deeper water—probably during certain sets of tides when bivalve larvæ are ready to settle—or may enclose a body of relatively still water at all depths.

Consumption of Oxygen in Sea Water under Controlled Laboratory Conditions*

DURING a recent hydrographical cruise of the *Atlantis*, the oxygen consumption in samples of water taken from eighteen levels between surface and 4,600 metres depth at Station 2886 (32° 19' N., 65° 59' W.; June 19, 1937) was determined under controlled laboratory conditions. Two glass bottles (with ground-glass stoppers) were filled from each of the Nansen water bottles as soon as they were brought on deck; one set of eighteen samples was stored at a temperature of 11° in an electric refrigerator and the other set at a temperature of 24° in the laboratory. After ten days of storage in darkness, oxygen contents of the two sets of samples were determined and subtractions of these values from initial oxygen contents of the samples gave results we have termed oxygen consumption.

Fig. 1.

OXYGEN CONSUMPTION IN C.C. PER LITRE PER YEAR (OBTAINED BY MULTIPLYING MEAN DAILY VALUES BY 365) FOR VARIOUS DEPTHS SHOWN BY HORIZONTAL LINES REFERRED TO TOP SCALE; VERTICAL DISTRIBUTION OF OXYGEN, RIGHT CURVE REFERRED TO BOTTOM SCALE; VERTICAL DISTRIBUTION OF TEMPERATURE, LEFT CURVE, REFERRED TO TOP SCALE. DATA FROM *Atlantis* STATION 2886

The oxygen consumption at 24° ranged from 0.058 to 0.165 c.c. per litre per day, and at 11° it ranged 0.020 to 0.069 c.c. per litre per day; higher values characterized water from levels below 1000 metres depth. The average oxygen consumption of all eighteen samples incubated at 24° was 0.1224 c.c. per litre per day, and for those at 11° it was 0.0487 c.c. per litre per day.

In an attempt to estimate what the oxygen consumption would have been if the samples of water had been incubated at their respective observed temperatures *in situ* (Fig. 1), it was assumed that the

* Contribution No. 151 from the Woods Hole Oceanographic Institution.

variation in oxygen consumption with temperature (between 25° and 2°) was of the form :

$$(1) \quad \ln k = c - \frac{A}{T};$$

which equation after being differentiated and then integrated between the limits k_1 , T_1 , and k_2 , T_2 , results in a form of the Arrhenius equation :

$$(2) \quad \ln \frac{k_2}{k_1} = \frac{Q}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right),$$

which frequently represents in a satisfactory manner the effect of temperature on biological reactions over limited temperature ranges.

Upon determination of the constant Q (R is the gas constant) from the average consumption values at 24° and 11°, each of the 18 pairs of values obtained at these temperatures were reduced by means of the Arrhenius equation to values corresponding to observed temperatures (range 25°-2°) at the depths from which the samples were taken, and the means of each pair of values (after multiplying by 365) are plotted against depth in Fig. 1. It is realized that this method of extrapolation may not hold for this particular phenomenon over the entire temperature range of 25° to 2°, but it does furnish an approximation.

The results (Fig. 1) after reduction are too high, particularly in the deeper levels, to be used in estimating oxygen consumption *in situ* in the water column itself. For example, at Station 2886, water from the minimum oxygen layer (less than 60 per cent saturated, occurring approximately between depths of 700 and 1000 metres) had an average daily adjusted oxygen consumption of 0.0363 c.c. per litre, which is about 32 times greater than the value of 0.42 c.c. per litre per year previously estimated for this layer; and water from between 1000 and 2000 metres had an adjusted daily consumption in the laboratory of 0.0385 c.c. per litre, which is more than 100 times greater than the more reasonable previously estimated value of 0.103 c.c. per litre per year for this part of the water column.

Thus, it appears that conditions in the sea, other than temperature, restrict the rate of oxygen consumption, and the above results are of interest since they indicate the potential rates of oxygen consumption throughout a water column of the sea when its equilibrium is disturbed by laboratory conditions.

Role of Heteroauxones in Legume Nodule Formation, Beneficial Host Effects of Nodules, and Soil Fertility

FOLLOWING identification of β -indolacetic acid¹ as a constituent of ether extracts of cultures of *Rhizobium phaseoli* in dextrose-bacto-tryptophane and in dextrose-bacto-tryptophane-peptone broths, these crude extracts were tested for auxones by applications to coleoptiles of *Avena*, and to hypocotyls and internodes of *Phaseolus vulgaris*, var. Red Kidney. The tests were strongly positive. Thus far we have been unable to determine whether β -indolacetic acid is the only heteroauxone in the preparations because of the scarcity of material.

Further, extraction of nodules of spontaneously infected Red Kidney bean plants first with acidulated 95 per cent alcohol (in which the nodules were ground

with pumice) and then with peroxide-free ether has yielded preparations which feebly affect growth of coleoptiles of *Avena* and of hypocotyls and internodes of the Red Kidney bean. Thimann's² method of extraction with acidulated chloroform probably will reveal a higher auxone content. Possibly the lot of nodules extracted was too old on the average to give a maximum auxone yield and possibly the sample used (50 gm.) was too small. Work is under way with larger and younger samples and with other methods of extraction. Tests with ferric chloride, hydrochloric acid and amyl alcohol indicate β -indolacetic acid as a nodular constituent. Unfortunately, the test is made with difficulty and uncertainty because of the dark colour of the crude extracts. Until more material and better tests are available, it will be impossible to identify β -indolacetic acid more positively or to determine whether the extracts contain growth substances other than β -indolacetic acid.

In conjunction with our findings¹ that pure β -indolacetic acid, applied in different concentrations and amounts in lanolin paste to primary roots of Red Kidney bean induces: (1) positive bending; (2) coiling; (3) retardation or suppression of root elongation; (4) premature and excessive lateral root initiation; (5) local diameter increase and nodulation, and with Thimann's³ findings that pea nodules are hyperauxonic in relation to normal healthy pea roots and that β -indolacetic acid incites nodulation in roots of *Pisum sativum*, our new findings indicate that β -indolacetic acid is one of the chemical agents, if not the agent, responsible for incitation of nodulation in susceptible hosts by *Rhizobium phaseoli* and other nodule-forming organisms.

The relative yields of total crude extracts from equal weights of nodules and of healthy roots as well as the greater growth-affecting capacity of the former, indicate hyperauxony for the nodules. These observations, together with Thimann's³ report that nodules of pea have a greater auxone content than non-infected root tips of the pea, seem to support the hypothesis¹ that tumours (including callus and galls) are brought about by local hyperauxony. This may be due to autoauxones, to heteroauxones, or to both added to the normal autoauxone content.

Coupled with our earlier findings¹ that β -indolacetic acid applied experimentally to the bean may augment or be in part a substitute for its autoauxones, the results reported here suggested the hypothesis that the beneficial effects of suitable concentrations of β -indolacetic acid and other auxones acting as heteroauxones may account in part for the characteristically beneficial effects of: (1) nodules for some host plants; (2) green manuring with nodule-bearing plants; (3) fertilizing with manures rich in dung and urine, or with compost; (4) humus soils; and (5) mycorrhizal fungi for some host plants.

This research was supported in part by a grant from the Rockefeller Foundation to the University of Chicago. Miss Virginia Eggers executed the growth tests. Prof. F. C. Koch kindly permitted use of space and equipment of his biochemical laboratory for execution of the extractions.

Structure of a New System of CO Bands

IN a previous note¹ the discovery of a new system of red-degraded CO bands, placed just before the heads of the violet-degraded Third Positive system, was reported. Inspection and measurement of high-dispersion spectrograms now show that the new bands have a structure appropriate to a $^3\Sigma \rightarrow ^3\Pi$ band-system, the lower state being the $a^3\Pi$ state, which is the usual final state of the CO triplet systems. The upper $^3\Sigma$ levels of the new bands lie about 88705 cm^{-1} and 85885 cm^{-1} above the CO ground state; they have observable spin-splittings and rotational constants $B' = 0.7$ to 0.8 cm^{-1} . The system may tentatively be designated as $f^3\Sigma \rightarrow a^3\Pi$. It may be considered, however, as probably due to transitions from the higher vibrational levels of $a^3\Sigma$ to the lower vibrational levels of $a^3\Pi$. For, within the heights of the initial levels $f^3\Sigma$ of the new bands occur also the initial levels $b^3\Sigma$ of the Third Positive bands, and the latter are strongly perturbed, as has already been established², by vibrational levels of the $a^3\Sigma$ state, for which we have predicted term values and rotational constants of the magnitude now observed for the new bands.

Rotational analysis and details will be published shortly elsewhere.

L-Emission Bands of Zinc, Copper, Nickel and Cobalt

I HAVE studied the intensity of the L-emission bands of metals from Co (27) to Zn (30). The apparatus used was a vacuum spectrograph using a bent crystal of mica, and the source of the radiation was an X-ray tube.

Fig. 1

To obtain the actual intensity distribution of the emitted radiation, the plate was calibrated by a method already described¹. The curves giving the intensity of the L_α bands against energy (in electron-volts) are shown in Fig. 1.

It is well known that the L-emission bands are emitted when M_{IV} , γ -electrons make transitions into the L_{II} , m -levels ($L_{\alpha_{1,2}}$ and L_{β_1}). There are also transitions of N_I -electrons into the L_{II} , m -levels. For these metals the N_I - or $4s$ -electrons are the conduction electrons, and occupy levels which overlap in energy those of the M_{IV} , γ - or $3d$ -electrons.² Thus the observed bands represent transitions of both $3d$ - and $4s$ -electrons. But for copper and zinc, unfortunately, the short wave-length ends of the bands, which are probably due to the $4s$ -electrons, are completely masked by satellites, which are strongly enhanced by the reorganization of the atom on account of the Auger effect³, L_I-L_{III} .

The position of the short wave-length edge of the L_α -bands may be estimated from the L-absorption spectra, and is given by the wave-length of the slope of the absorption curve near the minimum absorption. For copper, we can deduce from the absorption curve of Sandström⁴ that the edge of the L_α -emission band is given by the arrow marked on Fig. 1. From the comparison of the L-emission and L-absorption bands it is obvious that the width of the L_α -band is about 5 eV.

M-Emission Bands of Zinc, Copper and Nickel

WE have had the opportunity of seeing Dr. Farineau's letter before it was sent to press. We have recently observed the M-emission bands of nickel, copper and zinc metals, and it seems worth while to add a note, since the two sets of results, especially taken together, allow one to draw certain conclusions about the structure of the $3d$ - and $4s$ (conduction)-electron bands in these metals.

Our plates, taken with a concave grating spectrograph in the region 180–210 Å. and with an X-ray tube run at 3,000 v. as source, give results which, on a scale of energy, are almost identical with Farineau's L-emission bands. This is good evidence that, apart from transition probability factors, the curves represent features of the density-functions of the combined $3d$ -conduction-levels of the

metals. We also obtain for zinc and copper the peaks marked α' and α'' by him. But, contrary to his conclusion, when we compare the wave-lengths of points on the M-emission bands with the wave-lengths of the M-absorption edges which we have determined¹, we

arrive at the definite result that for both copper and zinc the peaks marked α' are part of the main emission band, only the α' peaks being satellites. Also it would, in the present case, be difficult to understand how the Auger mechanism could account for more than one satellite. A wave-length error, either in the L -absorption or the L -emission band of copper, seems the most likely explanation of the discrepancy.

If the α' peaks are to be included in the main bands, the shapes of the L - (or M -) emission bands, free from satellites, can be fairly accurately gauged from Farineau's Fig. 1, except in the case of zinc. Two points of interest stand out. (1) The curves show the shifting of the main peak (certainly due to $3d$ -electrons, which form a shell, incomplete for cobalt and nickel but complete for copper and zinc) towards the low energy end of the band as we pass from nickel to zinc. It is true that the resolving power of the method is not very good, being limited by the Auger broadening of the excited state. The unsharpness of the high-energy edge of the main bands gives a measure of this broadening. (2) The total breadths of the bands obviously represent the energy-spread

of the conduction ($4s$) electrons. For copper, it may be taken as $8\frac{1}{2}$ volts, including the α' peak, but correcting for the unsharpness of the edge. It is found that this is only a little greater than the breadth of 7 volts calculated, assuming one conduction electron per atom, on the elementary Sommerfeld theory (this correspondence is fairly general¹).

Now nickel and copper have the same crystal structure and almost the same lattice constant. So, from the present point of view, they differ only in the number N of conduction electrons per atom. Since the band-width is proportional to $N^{2/3}$, the energy-spread (6 volts) for the nickel band allows us to determine N for nickel as 0.59. This agrees excellently with the value postulated to explain the magnetic properties².

Points from Foregoing Letters

AN account of the Kyoto University expedition to Peru to observe the total solar eclipse of June 8, 1937, is given by Prof. Issei Yamamoto, who states that excellent photographs showing the structure of the inner corona were obtained by means of a ten-metre camera.

A graph showing that the resistance of zinc-blende, after excitation by blue light and 'quenching' by heat or infra-red light, decreases linearly with time is submitted by Dr. A. L. Reimann. The author infers that the electrons experience increasing difficulty in finding 'positive holes' to combine with as quenching proceeds. The linear rate of decay of the phosphorescence of zinc-blende, the author states, also agrees with this view. An outline of a mechanism of conduction is sketched, which seems necessarily to follow from the decay data, together with the results of early work on other photo-conductivity phenomena by Gudden and Pohl.

Drs. F. G. Mann and A. F. Wells show that aliphatic trialkyl phosphines and arsines unite with cuprous and argentous iodides to give fourfold molecules, $[R_3P(As) \rightarrow CuI]_4$ and $[R_3P(As) \rightarrow AgI]_4$, the structure of which has been determined in detail. Aurous halides give, however, the simple compounds of type $[R_3P(As) \rightarrow AuX]$, the phosphine members of which can be distilled without decomposition.

Prof. K. C. Bailey states that a gas flame 5-6 inches high can be extinguished by a jet of coal gas from a cylinder, without the jet being ignited. He infers that coal gas from a cylinder, bursting during a fire, may extinguish the fire locally, and thus make an opportunity of mingling with the air, and forming an explosive mixture, possibly with disastrous results.

Further work by Prof. A. E. Braunstein and M. G. Kritsmann on the transference of an amino group and two hydrogens from glutamic to pyruvic acid (with the formation of alanine and ketoglutaric acid), shows that the reaction is a reversible one. The enzyme responsible for the process occurs in various organs (muscle, brain, liver, etc.). The exchange of

amino group and hydrogen atoms takes place between other similar molecular couples, provided either the amino- or the ketoacid has two carboxylic groups.

Prof. F. A. Paneth brings evidence to prove that the number of stones, of one gram weight and heavier, in the Pultusk meteorite shower was of the order of 100,000. He also discusses the correct spelling of "Widmanstätten figures" (etching-patterns on iron meteorites).

It has been found that prolactin, a hormone stimulating milk production, will cause growth of the crop glands of the pigeon. Drs. S. J. Folley and P. White now find that if the pigeons are previously given injections of one of the female sex hormones, oestradiol monobenzoate, a marked inhibition of the crop gland response to prolactin is observed.

Prof. J. H. Orton states that the spatfall of the cockle is observed in localities where slack and eddy waters occur, that is, where tidal streams meet or where banks shelter a stretch of ground from prevailing winds. As many as 100,000 young cockles per square metre may occur in the centre of such areas.

The consumption of oxygen in sea water (that is, the amount of oxygen disappearing after ten days from samples of sea water obtained from various depths and kept under controlled laboratory conditions) has been determined by H. R. Seiwel. It appears that conditions in the sea, other than temperature, restrict the rate of oxygen consumption as found in the laboratory, since some of the results obtained, particularly for the deeper levels, are much too high as compared with previous estimates.

Prof. George K. K. Link reports that *Rhizobium phaseoli*, the bacterial incitant of nodulation of bean roots, produces the heteroauxone β -indolacetic acid when grown in pure culture in tryptophane-containing broths. He finds also that nodule extracts contain β -indolacetic acid, which may account for nodule production and for the beneficial effects of green manuring with nodule-bearing plants, and of humus soils, manures and mycorrhizal fungi.

Research Items

Canoes of Oceania

DR. A. C. HADDON and MR. JAMES HORNELL have made a detailed study of the canoes of Oceania, of which the first volume by Mr. James Hornell, dealing with the canoes of Polynesia, Fiji and Micronesia (Bernice P. Bishop Museum, Honolulu, *Special Publications* 27) is based in part on personal investigations in certain of the islands in 1924-25, in part on an exhaustive and critical examination of references in early travel literature with its illustrations, as well as of the models which are preserved in museums. References in early literature are usually inadequate, while the illustrations and the models are often inaccurate. Problems of distribution and dispersal will be considered by Dr. Haddon in a third volume. From the present collection of facts certain general conclusions as to population movements in Polynesia emerge. Two classes of vessel have to be taken into account, the outrigger and the double canoe. In outrigger canoes, in addition to rig and form of hull, the number of outrigger booms and the method of attachment to the float must be considered; in the double canoe the form and relative proportion of the hulls. The fundamental canoe types are reducible to three: (1) Proto-Polynesian, in which the hull has pointed ends, inclined upwards, but little emphasized, is strengthened by inserted ribs, and the canoe is rigged with a primitive sprit-sail; (2) Melanesoid-Polynesian, with head low and stern curved up high, profusely ornamented with carving, the sail a primitive sprit-sail, triangular or sub-triangular; (3) Tangaroan, plank-built hull with ribs tied to ridges, the planks sewn together through holes, rigged with a primitive lateen sail. This third type was probably introduced by an Indonesian people who worshipped Tangaroa. From the evidence of the canoes it may be argued that the Proto-Polynesians reached Polynesia direct from Indonesia by way of Micronesia; and not after coasting along the shores of the Melanesian Islands as is held in the generally accepted view.

Fishes of Paraguay

A REMARKABLE similarity exists between the fish fauna of the La Plata and that of the Amazon basin, and two explanations have been offered: that the two faunas represent the same initial stock, which by migration over the marshy uplands between the Tapajós and the Paraguay or across the low divide between the latter and the Guaporé peopled the two river basins; or that the two faunas illustrate the parallel evolution of two distinct stocks. A contribution to a solution of the problem is made by Prof. Nathan E. Pearson, who has listed the fishes of the Paraguayan basins, and considers that it is unnecessary to assume parallel evolution to explain their Amazonian resemblances (*Pub. Calif. Acad. Sci.*, 23, 99; 1937). Migration is a sufficient explanation. The fishes entered South America some time during the Tertiary Period and crossed the low Amazon valley and a highland divide to enter Paraguay. The Rio Guaporé and other tributaries of the Amazon seem to have

afforded the migratory paths. At the present time, the possibility of such migration has been cut off, since the fall in the volume of the streams flowing from the highlands of Matto has given rise to an effective barrier, but the nature of the fishes on the two slopes of that barrier indicate that it is of recent origin.

Life-History of *Apophallus venustus*

FOLLOWING a previous account of its morphology and taxonomy, T. W. M. Cameron has published an account of the life-history and bionomics of the trematode, *Apophallus venustus* (*Canadian J. Res.*, 15, No. 2; 1937). This trematode is endemic in the Lower Ottawa Valley, and has been found in cats, dogs and racoons. It has also been found in the great blue heron, though not in several other species of fish-eating birds examined. The first host is an operculate snail, and the only species discovered naturally infected was *Goniobasis lioscoens*, in which the percentage of infection may reach 31.6. The metacercaria stage lives in the second host, a fish, and eleven out of twelve species of freshwater fish when eaten by cats under controlled conditions were found to be capable of carrying infection. The metacercariae are present in the subcutaneous tissue or the muscles. The adult in the cat lives principally in the ileum, and in the laboratory all infected cats lost their infection during the winter, so that the reservoir would appear to be the fish.

Lac in Malaya

ATTEMPTS to cultivate the lac insect (*Laccifer lacca*) outside India have been made from time to time. The most recent effort has been tried out in Malaya and an account of the experiment is given by Mr. N. C. E. Miller in Scientific Series No. 19 (1937) of the Department of Agriculture, Straits Settlements and Federated Malay States. Consignments of brood lac for the work were obtained from the Lac Research Institute, Nankun, India, in which country the insect has been propagated for several hundred years. It may be added that about 25,000 tons of shellac products are exported annually from India to all parts of the world. The consignments received in Malaya were used to inoculate rain trees (*Enterolobium saman*), *Cajanus indicus*, *Zizyphus jujuba* and plantation rubber trees. The outcome of the experiments was disappointing. It was decided that the climatic conditions in Malaya, especially the high degree of humidity, and other circumstances are wholly unsuitable. The very young insects, or swarming larvae, showed a prominent tendency to colonize the host trees towards or on the main stems and to neglect the young growing shoots. Owing to this erratic behaviour and the rapid suberization of the branches, they failed to survive. Another contributing cause of the failure was the prevalence of a chalcid parasite of destructive propensities. These causes, and the inroads made by synthetic substitutes for resins, are stated to have led to the abandonment of any further trials.

Endosperm and Embryo in Reciprocal Cereal Crosses

IN reciprocal crosses of plants with different chromosome multiples, the more successful cross is usually the one in which the high chromosome number comes from the female parent. Messrs. J. W. Boyes and W. P. Thompson (*J. Genet.*, 34, No. 2) discuss this subject in relation to cereals, recording a series of observations on embryo and endosperm development in reciprocal hybrids between *Triticum vulgare* and *T. durum*, *T. vulgare* and *T. dicoccum*, *T. spelta* and *T. monococcum*, as well as back-crosses and crosses between wheat and rye. Chinese wheat, unlike other varieties, can be readily crossed with rye pollen. In the crosses low-chromosome female $\times$ high-chromosome male, although there is a higher rate of endosperm growth, abnormalities in the endosperm are frequent. These include nuclei of unusual sizes, abnormal structure and irregular shapes, weakly staining cytoplasm and persistent non-cellular regions. The reciprocal crosses do not show these abnormalities, except in the widest crosses. The embryo, on the contrary, is healthy in development in all except the widest crosses, and the reciprocals show very little difference. In rye (7 chromosomes) $\times$ wheat (21), fertilization rarely occurs although the pollen germinates well on the rye stigma. In the back-crosses F_1 female $\times$ *vulgare* male, the endosperm varies widely from normal to conspicuously abnormal. This is attributed to a variable amount of chromosome unbalance, which is believed to be one of the causes of the differences in the endosperm of reciprocal crosses.

Diseases of Ornamental Plants

THE *Gardeners' Chronicle* of July 10 announces the appearance of two fungus diseases upon ornamental plants. Mr. D. E. Green directs attention to a downy mildew of snapdragons caused by *Peronospora Anthrini*. The disease has been known in southern Ireland, and has now appeared in England. It checks the growth of young shoots, has a tendency to curl the leaves downwards, and often causes the plant to send out many small shoots from the base. Messrs. A. Beaumont and P. H. Gregory describe a leaf-spot disease of *Gerbera Jamesoni*, a plant which can be grown outside for market in Devon and Cornwall. The fungus *Ascochyta Geberae* attacks the leaves, and produces brown spots with margins of purple. Pycnidia of the fungus are embedded within the tissue of the spots. The disease appeared in Italy in 1913, and has not since been described until its occurrence in Cornwall in 1936.

Protective Spray Deposits

THE efficiency of protective insecticides and fungicides depends largely on the amount of spray material which remains on the foliage immediately after spraying, and the degree to which this resists the various agencies which tend to remove it. Fajans and Martin (*J. Pom. and Hort. Sci.*, 15, 1, 1-24; 1937) denote these two properties by the terms 'initial retention' and 'tenacity' respectively. They describe laboratory experiments from which are evaluated the effects of a number of spray supplements, particularly wetting agents, on initial retention and tenacity, the supplements being added to spray materials used in the form of suspensions. In the majority of the systems examined, the initial retention of a suspension was found to be the same as that of the aqueous phase,

but in some cases the latter was reduced by the presence of the solid particles. This reduction seems to be related to an effect on the wetting and spreading properties of the spray, but is not independent of the nature of the surface sprayed. The tenacity of the spray deposit is dependent upon the characters of the spray supplement, the solid particles and the surface sprayed. It is comparatively higher on surfaces wetted with difficulty and is enhanced by oils, both hydrocarbon and glyceride. Highly surface-active supplements, especially at high concentrations, reduce tenacity, whilst those like gelatine and lime casein, which yield residues insoluble in cold water, have a favourable effect. These conclusions were tested in the field by treating a crop of potatoes against blight (*Phytophthora infestans*) with cuprous oxide sprays to which ten different spray supplements were added. A high degree of correlation was obtained between the amounts of spray residue and the control of blight.

Meteorology of American Floods

THE unprecedented floods on the Ohio and lower Mississippi Rivers last winter, coming so soon after the exceptional floods of March-April 1936 in the middle and north Atlantic States, have led C. F. Brooks and A. H. Tieszen to a study of the meteorology of such floods. An account of their work has appeared under the heading "The Meteorology of Great Floods in the Eastern United States" (*Geographical Rev.*, 27, No. 2, April 1937) and has recently been reprinted as a separate paper. The flood of 1937, with its monetary loss of at least six hundred million dollars, is, according to these writers, the greatest American flood on record. They find that two meteorological features are common to all great floods such as those of 1882, 1889, 1903, 1913, 1922 and 1927, and those of the last two years, namely, "a rapid and continuing flow of moist tropical air into the country and a frequent and persistent elevation of this tropical current by a colder air mass over the same region". This arises from a persistent anticyclone over the western part of the North Atlantic and another over the central or northern interior of the United States, or a little farther to the west. The one drives tropical air northwards, the other polar air southwards, and ascent of the warm air is continuous and sometimes violent along the front between the two. The importance of the weather before the heavy rains that are the immediate cause of the flood is pointed out; a rapid run-off is favoured both by wet weather which saturates the ground and by severe frost that makes it impermeable; on the other hand, dense vegetation and a dry soil or a deep cover of snow over unfrozen ground may entirely absorb five inches or more of rainfall. The fact that great floods are confined to the winter and spring is to be attributed to the vegetation that protects the summer and autumn by hindering run-off and rapidly using ground water.

Young's Modulus Apparatus

THE August issue of the *Journal of Scientific Instruments* contains a description of an interferometer apparatus for the accurate determination of Young's modulus over a wide range of temperature, devised by Mr. J. W. Cuthbertson of the University of Manchester. A bar of the material about 9 cm. $\times$ 0.8 cm. $\times$ 0.3 cm. is supported symmetrically on parallel horizontal knife edges about 4 cm. apart; the

load is applied by needle points, near the ends of the bar, which support a bar to whose centre the load is applied by weights or by a lever. The rise of the centre of the test bar is transmitted by an invar wire to a tripod the other two legs of which are supported by hole and groove in a fixed plate. The tripod carries the lower plate of an interferometer the upper plate of which is fixed. The interference bands in reflected light are observed in a microscope and the number which pass a fixed line, as either load or temperature is gradually changed, is counted to get the rise of the centre of the bar. The bar and its supports are suspended in an oil bath by rods of invar bolted to horizontal iron beams which carry the interference apparatus. A few typical results are given.

Detection of Destructive Larvæ in Timber

In the National Physical Laboratory Report for 1936 (London: H.M. Stationary Office. 2s. 6d.) Dr. R. L. Smith-Rose, the head of the radio department, describes an acoustic-electrical equipment for detecting destructive larvæ in timber. At the request of the Forest Products Research Laboratory, he explored the possibilities of applying microphone and amplifier technique to the detection of larvæ in specimens of timber. The first experiments showed that there was little likelihood of the successful application of a method of this kind to the detection of larvæ in buildings or growing timber, owing to the faintness of the sounds concerned relatively to the associated background noises. Further experiments carried out when the specimens were housed in a sound-proof container were promising. A suitable equipment was designed and constructed. The specimen of timber to be examined was placed in a sound-proof container with a suitable control specimen and a microphone was laid on each. When the specimen contained larvæ, the noises made by these could in general be readily distinguished from the more uniform background noise of the amplifier itself. In some instances different larvæ could be distinguished by the differences in the sounds they made. A description of the equipment used has been prepared for publication.

Reflection of Radio Waves in the Atmosphere

THE well-established reflection of radio waves in the upper atmosphere takes place at apparent heights of 100–200 km. and it is generally believed that the damping effect of atomic collisions on ionic motion prevents reflection from ionized layers much lower than this. R. A. Watson-Watt, A. F. Wilkins and E. G. Bowen (*Proc. Roy. Soc., A*, 161, 181) have now observed reflection from much lower levels. They used the pulse technique, refined so that a very short pulse was transmitted upwards and echoes of very short delay could be observed on a cathode ray tube. Continuous records and 'snap' observations were both used. The observers were able to detect a series of reflections which they interpret as arising from a few layers at height about 10 km., possessing reflection coefficients of the order 0.7 (for 50 m. waves and vertical incidence). The layers are fairly persistent in time and occur both by night and by day. The records also reveal reflections from the Appleton D region (50–90 km.) and from stratospheric layers at about 30 km. A feature of D region reflection is the occurrence of sporadic bursts of reflection lasting a few seconds. The appearance of

a 30 km. reflecting layer has on several occasions been correlated with thunderstorms, and an appendix to the paper shows that the 'runaway electrons' predicted by C. T. R. Wilson should be bent round by the earth's magnetic field and might produce ionization of the type required. The occurrence of these low reflecting layers may have some practical bearing on short-wave transmission and in particular on television phenomena.

Concentration of Nitrogen Isotope

By using the exchange reaction between ammonium sulphate and ammonia gas, H. C. Urey, M. Fox, J. R. Huffman and H. G. Thode (*J. Amer. Chem. Soc.*, 59, 1407; 1937) have been able to concentrate the heavy isotope of nitrogen, ^{15}N , for use in biochemical and chemical investigations. A solution of ammonium sulphate was pumped into the top of a fractionating column under low pressure, ammonia was liberated from the salt at the bottom by addition of caustic soda, and the ammonia gas stripped by a packed column. This ammonia was fed back to the bottom of the column and escaped at the top. As a result of a 13-day run, nitrogen containing 2.54 per cent of ^{15}N was obtained, an increase of concentration of 6½-fold. The samples were analysed by the Bleakney mass spectrometer, giving an accuracy of 0.02 per cent ^{15}N .

Structure of Water

THE open tridymite-like structure of ice as regards the distribution of the oxygen atoms appears to have been definitely established by Barnes, and Pauling's explanation of the discrepancy between the entropies of ice calculated by Nernst's theorem and statistical methods indicates that the hydrogens are unequally spaced between the oxygens. Present theory, as developed by Bernal and Fowler and modified by Katsoff and others, considers liquid water at ordinary temperatures as having essentially a broken-down ice structure, permitting closer packing with a considerable amount of co-ordination persisting through hydrogen bonds. This co-ordination decreases with rising temperature or addition of electrolytes. According to Pauling, two of the four hydrogens which surround a four-co-ordinated oxygen atom tetrahedrally are bonded to it in much the same manner as in an isolated water molecule, while the other two hydrogens are at a greater distance (1.77 Å. instead of 0.99 Å.) from the oxygen and essentially bonded to other oxygen atoms. The oxygen nucleus in ice has four oxygens tetrahedrally bonded at 2.76 Å., with a proton along each O—O axis. An examination of the Raman spectra of ice at 0°, of water over a wide range of temperatures, and of deuterium oxide, has been made by P. O. Cross, J. Burnham and P. A. Leighton (*J. Amer. Chem. Soc.*, 59, 1134; 1937). The results are interpreted on the basis of a model consisting of O—H oscillators perturbed by various types of co-ordination. A semi-empirical treatment indicates that in ice at 0°, the four-co-ordinated structure predominates, but appreciable amounts of three- and two-co-ordinated molecules are present. Water is rather more than two-co-ordinated at 25°–90°, and is slightly less co-ordinated than deuterium oxide, two-co-ordinated structures predominating in both liquids. Little significance is attached to the existence of definite polymolecular structures such as $(\text{H}_2\text{O})_n$, $(\text{H}_2\text{O})_2$, frequently postulated as existing in liquid water.

Egyptian University Scientific Expedition to South-West Arabia

By Dr. S. A. Huzayyin

BETWEEN April and October 1936 the Egyptian University of Cairo sent out a scientific expedition to Yaman and Hadhramaut. It consisted of four members, and was intended to carry out researches in the fields of geology, physiography, archaeology, anthropology and entomology. The expedition covered a distance of some 2,500 kilometres and was able to carry out intensive researches at various localities both on the High Plateau of Yaman and in the interior of Hadhramaut. The material brought back has not been studied in detail as yet; but a preliminary note can be given here.

GEOLOGY

One of the expedition's main aims was to work out certain problems connected with the geological history of the southern borders of the Red Sea. We worked at a number of points along the lines of rifting both south and west of the Yaman Plateau, where the old crystalline rocks (schists and granites) of the base were exposed under later (secondary and tertiary) sediments and lavas. The successive horizons of the tertiary traps of the High Plateau were carefully examined and specimens collected. In north-east Yaman we worked chiefly on Jurassic limestones and Nubian sandstones, and a large collection of fossils was made from the successive zones of the former. The interior of Hadhramaut was found to have a relatively simple structure and to consist mostly of Eocene limestones on earlier unfossiliferous sandstones. We hope that new evidence from the lower part of the Eocene may throw useful light on the date of the trap volcanic series of tertiaries in south-west Arabia.

PHYSIOGRAPHY

Pleistocene geology proved to be quite interesting. We worked chiefly on the middle parts of the valleys, which were relatively independent of changes in base (sea) level. Two physiographic cycles were established, the first being by far the more pronounced. Valleys with sloping sides were first cut and then filled with coarse gravels which now rise (usually in two or more terraces) to some 30 m. above the beds of the streams. During this stage there was a good deal of lateral wash and erosion in the middle parts of the valleys, and this erosion was probably responsible for the sloping sides of the V-shaped valleys. The gravels were examined at a large number of exposures, but unfortunately they produced only one or two specimens of pre-Challeian appearance.

The second physiographic cycle was associated first with the cutting of new steep-sided valleys *emboites* in the older gravels, and then with the filling in of these new valleys with soft sediments of silt. Deposition was much more regular and there was very little lateral wash in the middle parts of the new valley-beds. The discharge during the depositional phase of the second cycle was much less than that during the depositional phase of the first cycle, as only

soft silt could be carried to the middle courses of the streams. The two cycles were separated by a phase which was marked by extensive volcanic activity, especially in north-east Yaman, where the lava spreads always cover the old gravels and underlie the silts. The second cycle was followed by erosion, during which new torrential beds were cut into the silts (sometimes producing a series of erosional terraces). There has also been a still more recent (historical) outburst of volcanic activity (on a much more limited scale), the accompanying features of which are still noticeable in hot springs, etc.

We were able to associate the two physiographic cycles (or at least their depositional phases) with pluvial episodes. During Quaternary times this corner of Arabia seems to have had two major Pluvials separated by an Interpluvial. It was not possible to work out the stages of the first Pluvial, which was a prolonged one, and which must have had more than one sub-maximum (as shown by terraces); but there is presumptive evidence from one or two places that the second Pluvial may have had two sub-maxima separated by an Intrapluvial. In recent times there was a new wet phase (shown by archaeological and other evidence), which we believe to have continued well into the Christian era (perhaps to the fifth century A.D.).

ARCHAEOLOGY

The south-west plateau of Arabia proved to be singularly poor in prehistoric remains. Perhaps the great height (mainly above 1,500 m.) and the unfavourable climatic conditions during pluvial episodes contributed to this. It is to be recalled that very few remains have thus far been found at the high altitudes (above 8,000 ft.) of the opposite coasts of East Africa. We have carefully examined gravel exposures and have carried out experimental excavations at no fewer than fifteen caves and rock shelters in Yaman and Hadhramaut, but the results were largely negative. Surface specimens were looked for all along the route, but they were found only in very limited numbers and in particularly favourable localities; they belong typologically to Lower and Middle Palaeolithic and rarely to the Upper Palaeolithic. Whatever may have been the reasons, the scarcity of even surface finds shows that even if remains of prehistoric man may some day be forthcoming from this region, they will never be comparable in quantity with those from the African side. This reflects rather unfavourably on recent views put forward with regard to East Africa as a centre of cultural diffusion in Lower Palaeolithic times.

Remains relating to the early historic phase of the area were, on the other hand, particularly abundant. Work and excavations at a number of places in Yaman and Hadhramaut have yielded fairly illuminating results. New light is thrown on relations between south-west Arabia on one hand and the Hellenistic East and Graeco-Roman Egypt on the other, during the early centuries of the Christian era.

More than a hundred new Sabaitic inscriptions were copied and photographed. At three sites in the Aden and Hadhramaut protectorate, particularly the ruins of Reiboun (near Mash-had) there is, on the other hand, contacts with East Africa. Here we found an industry of obsidian (with some flint) in definite association with pottery and with Sabaito-Himyaritic inscriptions, all found in shallow kitchen midden-like remains and amongst ruins of ancient buildings and habitations. Some of the characters were actually inscribed on the pottery both before and after baking. The obsidian industry includes practically all the types and sub-types of the so-called final Palaeolithic and Neolithic cultures of East Africa—Wilton, Elmenteitan and Gumban. There are small nuclei, simple and retouched blades, truncated and notched ones, small backed knives, trapezoidal forms (in abundance), true lunates (less abundant), chisel-ended tools or *pièces écailées* ('sinew-frayers' of Dr. L. S. B. Leakey), borers, medium-size and small burins (but not the micro-burin proper) and scrapers of various descriptions (nucleiform, round, at end of blade, etc.). Yet there can be no doubt about the Sabaito-Himyarite date of this industry in south-west Arabia (the few centuries centring round the beginning of the Christian era).

Apart from inscriptions (on stone and on pottery) there are metal elements and beads of dating value. The pottery here is much more developed and varied than in East Africa, but this is to be expected in a country with more progressive civilization. One cannot argue from the evidence we have for the separation of the obsidian industry from the rest of the datable remains which must all have belonged at least to one and the same culture phase*. If this be so, the dates assigned by Dr. Leakey and others to the so-called final Palaeolithic and Neolithic industries of East Africa will have to be revised. It would be unreasonable to argue for a 'survival' into historic times of an obsidian and flint technique in south-west Arabia after it had been introduced from the African side at a final Palaeolithic date. It would be rather in this latter region (East Africa), which produced no such highly progressive civilizations as we know from south-west Arabia, that we should expect such 'persistence'. Perhaps many of the Microlithic elements of industries in East Africa may ultimately prove to be of comparatively recent historic date (Christian era).

We have also discovered, at a number of rock shelters in the Middle Wadi Hadhramaut, rock drawings (both animals and men) of both naturalistic and schematic styles. The former were associated with Himyaritic inscriptions (mostly names and cartouches), while the latter were of much more recent appearance. At the base of some of the rock shelters we found a flake and blade industry of flint which we have reason to associate with the first series of drawings.

ANTHROPOLOGY

Anthropometrical measurements were made of 1,350 male individuals, of whom 800 were studied in Yaman and 550 in Hadhramaut. More than 400 individuals were photographed full face and profile. The individuals are representative of the great majority of the tribes inhabiting the area, and useful light may be expected to be shed both on local distribution of anthropological features and types and on similarities and connexions with neighbouring areas in Asia and

Africa. Already interesting links are being worked out with Iran and the west Deccan. Local differences have also been worked out within both Yaman and Hadhramaut. The population of the northern part of the Yaman plateau is essentially mesocephalic, though it also shows certain features due to mixture. South Yaman, on the other hand, has broader heads. There is also a number of Jewish colonies in Yaman from whom representative groups were measured. In Hadhramaut we have a markedly brachycephalic type (very dominant, especially in the interior) and a mesocephalic one (especially on the coast). The broad heads of Hadhramaut show interesting anthropometrical features, and the roundness of their heads is primarily due to shortness (flattening of the back) rather than to width. Armenoid affinities among the broad heads of south Arabia are already known from previous observation and measurements (Bertram Thomas, etc.). The High Plateau of Yaman is practically free from prognathism, which becomes more and more marked as we go eastwards into Hadhramaut. We have reason to believe that this feature was not the result of crossing with Negroids from Africa, but represents an element brought from farther East. Special attention, however, has been paid to cases and areas of metisisation between Negroid and Arab types, especially in coastal regions. Some peoples of the coastal plains of west Yaman have been shown to have marked affinities with the Negroids of Africa, who, however, do not seem to have affected the High Plateau to any appreciable extent. Certain parts of the Hadhramaut coast are equally mixed, and even in the interior there are colonies of imported elements (for example, Negro soldier-slaves, Indo-Chinese and Chinese elements as slaves and wives brought back by enterprising merchants of Hadhramaut, etc.).

ENTOMOLOGY

Between five and six thousand specimens have been collected, and a large number of these were actually set in the field. They represent fauna from all the altitudes we have passed through (from sea-level to 3,500 m.). The identification of our specimens will inevitably be a long process, but it is hoped that fresh light may be thrown on the question of migration between adjacent parts of Africa and Asia in these regions. One of the chief topics we worked upon was the question of locust breeding-grounds and migrations, and already some useful results have been achieved in this direction.

In addition to these topics, members of the expedition carried out side-line investigations, such as the taking of a meteorological record during the journey (with as few breaks as possible), the collection of plants and small animals in localities which have not been visited before and of fishes and aquatic fauna from all streams and springs along the way, as well as the recording of observations on the general geography and ethnography of the lands and peoples in the areas visited.

*Should there be any chance of such a separation, however, the only possibility would be that at a posterior date poorer tribes took shelter among the Sabaito-Himyarite ruins and left their obsidian industry thoroughly mixed with earlier remains. In that case the lithic industry would be still more recent than the Sabaitic phase. There can be no possibility of the Sabaito-Himyarites having chosen for sites of their cities places where earlier obsidian and flint-using tribes left their kitchen midden and rubbish heaps.

The Location of Industry

THE attention which is now being given to the location of industry was reflected not only in Prof. P. Sargant Florence's presidential address to Section F (Economic Science and Statistics) of the British Association on September 3, but also in the discussion by the same Section on September 2 of problems of labour transference. Mr. H. C. Emmerson, assistant secretary to the Ministry of Labour, who opened the discussion in place of Mr. Humbert Wolfe, described the work which the Ministry of Labour has been carrying out since 1928 to assist the unemployed. Men and women from the depressed areas are given the first opportunity of vacancies in other areas and are assisted if necessary by free travel, special allowances and a lodging allowance. In 1936, no fewer than 20,000 men and 8,000 women were placed through the exchanges. A juvenile employment scheme was started in 1928, and Mr. Emmerson also described a household removal scheme by which a man is assisted to take his family to the place of his new employment, and a family removal scheme which sends members of one family to work in one place. 10,000 removals have taken place under the two schemes.

The Ministry of Labour's present policy is largely directed to the movement of workers to specific vacancies, and this was severely criticized by Mr. S. R. Dennison, of the University of Manchester, who argued that in spite of the success achieved the basic policy is sometimes wrong. Employers expect a higher standard of work from men supplied by the exchanges than from those recruited directly. Mr. Dennison believes that transference should be accelerated not during boom years but when there is a slump, and urged that the Ministry should be filling 80 per cent of the vacancies instead of the present 25 per cent. In Lancashire, the existence of a family income is a strong deterrent, and Mr. Dennison also considers that with the present policy a depressed area is left heavily weighted with unemployed in the lower and higher age groups, and in consequence with more dependants, a falling income and increased depression. In that direction complete evacuation is the only logical policy.

The social consequences of industrial transference were discussed in a paper by Mr. A. D. K. Owen. For communities from which transference has taken place on an appreciable scale, the most obvious consequence is either a diminution in population growth or an actual fall in population. Up to the present, the high rate of natural increase (due to relatively low death-rate and high birth-rate) in the areas from which most transference has taken place has compensated to some extent for the loss of population by migration. More important, however, are the modifications in the age-structure of the population resulting from migration. Industrial transferees are mostly young people; there has in consequence been a marked ageing of the population in the depressed areas, and this tendency will increase in the next few years. Moreover, as the transference is voluntary, it acts as a selective process which tends to lower the average quality of the population left behind. With some important exceptions, it is the more active and adventurous elements in the community which tend to migrate. The immediate effect

of transference is to reduce unemployment in the depressed areas from which it takes place, but the ultimate effect may well be different, especially if skilled or potentially skilled workers are transferred. Denudation of skilled workers or of the most promising young workers may actually increase unemployment by impeding the development of new industries and in time depressing existing industries still further. The development of new industries in the depressed areas has already involved the return of some skilled transferees.

Where transference has resulted in an appreciable fall in population, it has considerably eased the problem of overcrowding as well as reduced the pressure on local social services, but there are losses in institutional life as well as in rate income. For communities to which transference has taken place there is a valuable gain in population, which provides a basis for industrial expansion but also raises many difficult problems for local government authorities in the expanding areas. Overcrowding is very serious, as well as transport problems and the provision of a sufficient number of new schools. In spite of difficulties of assimilation and social friction, the introduction of large numbers of new workers and their families into fresh areas is socially invigorating, and the redistribution of the labour supply in relation to economic opportunities represents a considerable economic gain. On the other hand, there is some reason to believe that subsidized transference is artificially distorting the industrial structure of the country. For the community as a whole the greatest gain from industrial transference has been the salvaging of young workers from the deteriorating effect of long-continued unemployment, and this must be set against the waste of social capital in the areas from which transference takes place and the devitalization of provincial or even national culture. Mr. Owen considered industrial transference should continue along different lines related to a broad plan of national development which takes account of both economic and social factors.

Dr. O. A. Oesser, in a paper on psychological and sociological aspects of labour transference, first reviewed the problems involved in relation to the condition of the material available for transfer. Highly skilled workers are more easily transferred, provided jobs are available for which their training is adequate, not only because transfer from a more skilled to a less skilled job is easier than the reverse, but also because of their frequent tradition of emigration and their higher intelligence level, wider knowledge, training and flexibility. The type of educational system may also be a factor. The social and economic conditions of the areas between which transfer is to be made must next be considered. People can be moved from areas of lower to areas of higher standards of living, but local patriotism and reluctance to move may be obstacles, as well as traditions and a subjective social status of occupation. Finally, Dr. Oesser suggested that the condition and state of industries in the area must be considered in relation to those of Great Britain as a whole, and he used the jute industry as an example to illustrate the growth of new social patterns among the unemployed and the mobility of labour between occupations.

International Society of Leather Trades' Chemists

CONFERENCE AT COPENHAGEN

THE biennial conference of the International Society of Leather Trades' Chemists took place at Copenhagen on August 29-September 2, the meetings being held in the Technological Institute there. The president for the years 1938-39 is Mr. W. R. Atkin (England). It was announced that the Procter Memorial Research Fellowship Fund had reached a total of £3,400, and it was hoped to appoint the first research scholar in October 1938. It was also decided to institute a Procter Memorial Lecture to be delivered at all future conferences, and the first will be delivered in London in 1939. Dr. E. Scheil (France) was made an honorary member of the Society.

Several combined sessions were held with the German Internationalen Vereins der Leder Industrie Chemiker, before which many interesting communications were made.

Dr. K. Linderstrom-Lang gave the opening lecture on the constitution of proteins as elucidated by enzyme studies. Dr. Dorothy Jordan Lloyd followed with a paper on the swelling of structured proteins with special reference to the influence of the reticular tissue on the swelling of collagen in alkaline solutions.

Mr. W. R. Atkin discussed the titration curves of gelatin and collagen, pointing out that, by the application of the Procter-Wilson theory to the titration curve of gelatin, it was possible to construct a replica of the swelling curve of gelatin in hydrochloric acid. It was also demonstrated that the second isoelectric point of gelatin postulated by Wilson could not exist. Dr. F. Schneider gave a paper on the hide proteins, emphasizing that various hide proteins could be distinguished by determining their sugar and amino-

acid contents. Dr. F. Stather dealt with the technical problems of fat-liquoring and stuffing of leathers, while several aspects of the chemical testing of vegetable tanned leather were dealt with by Dr. V. Kubelka.

Mr. G. Parsy discussed the pH values of sulphonated oils, and a new electrode for pH determinations was demonstrated by J. Hangaard. Dr. D. Burton described a method for determining the amount of neutralizing agent required by a chrome leather, and Dr. K. H. Gustavson discussed the concept of the chrome-collagen compound as an internal complex salt. The tanning effect of polytungstic acid was described by Dr. C. Riess, and Dr. E. Elöd pointed out in his paper the use of polyvinyl alcohol as a substitute for proteins in tanning research experiments. Dr. G. Otto compared the titration curves of synthetic tannins with those of natural tannins, and Dr. W. Grassmann described a nephelometric micro-method for the identification and estimation of tannins.

Mr. A. Dohogne discussed the relative water permeabilities of sole leathers tanned by slow and rapid methods, and Dr. A. Miekerey described some work on the combination of lignin sulphonie acids with hide substance. The fractional extraction of pine bark was the subject of a paper by Dr. V. Nemes, while Dr. L. Pollak explained methods for the chemical control of hide soak liquors.

During the official banquet which followed the conference, Dr. E. Stiasny was presented with the first copy of a special "Festschrift" volume published to commemorate his sixty-fifth birthday, to which contributions have been made by well-known leather chemists throughout the world.

Metallurgy and the Aero Engine

THE sixteenth Autumn Lecture of the Institute of Metals was delivered by Dr. D. R. Pye, director of scientific research to the Air Ministry, on "Metallurgy and the Aero Engine", at the Sheffield meeting on September 6.

During recent years, there has been a remarkable increase in the power output from aero engines. A comparison of two engines of the same general type and cylinder capacity shows an increase in the last seven years of more than a hundred per cent. This increase has been achieved by improvements in the quality of the fuel, which allows the combustible mixture to be supplied by a supercharger at a higher pressure and temperature. A parallel improvement in the materials of construction to meet the severe conditions of temperature and mechanical loading has taken place, and there is scarcely one major component of the two engines of which either the material or its treatment has not been modified. The problems so far as they concern the metallurgist are both thermal and mechanical. It is fundamentally impossible greatly to increase the proportion of the heat generated which is turned into mechanical work.

The marked increase of power has, therefore, involved a corresponding increase in the waste heat which is to be removed. The piston, which must be receiving about forty per cent more heat, is a critical factor and the temperature attained on the piston is, from examination of the recrystallization of aluminium alloy pistons after use, of the order of 450° C.

The discovery of a new material of about the same specific gravity and thermal conductivity, but better able to maintain its strength at temperatures of 300° C. and above, would be one of major importance.

The increase of waste heat, combined with the chemical problems introduced by the use of lead tetra-ethyl in the fuel, has profoundly affected the metallurgy of the exhaust valve. In spite of great improvements in the steel, it is now necessary not only to transfer heat away from the valve head by means of hollow valves containing liquid, but also to coat the valve with special alloys to resist oxidation at the high temperatures involved. Improvements of sparking plugs involve interesting problems in which the engineer needs the help of the physicist.

On the mechanical side, the chief metallurgical problem of the aero engine is that of maintaining two surfaces rubbing together at high temperatures without seizure. This is essentially a problem of lubrication, but as the temperatures of the working surfaces increase, the viscosity of the oil gives less and less protection, and the nature of the metal surfaces themselves will play a more important part.

Working surfaces are never flat when considered in terms of molecular dimensions, and it becomes, therefore, of great importance to examine the possibility of the treatment of the surfaces in such a way as to render them less liable to seizure. The line taken by the engineer at present is to use one of the recognized methods of producing a hardened surface, but much further knowledge in this direction is still required. Beilby showed thirty-five years ago that during the polishing process the normal structure of metal is destroyed and the surface becomes amorphous. This conclusion has been confirmed by the recent work of Finch and Bowden. It has been shown that during the 'running-in' process a very thick Beilby layer of amorphous material is produced on the surface of a steel cylinder. Apart from the fact that observations have shown that a metal in the amorphous condition is harder and tougher than the crystalline variety, it is, in Dr. Pye's opinion, reasonable to suppose that an amorphous surface could be more easily protected from seizure by a thin oil film than could one of a crystalline character.

Such problems can only be successfully surmounted by the engineer with the advice of the physicist, and they are bound to assume a steadily greater importance where rubbing surfaces have to survive without seizure under high temperature conditions.

Science News a Century Ago

Faraday and Schönbein

ON September 21, 1837, Faraday wrote to Schönbein, from the Royal Institution, "Your very pleasant and acceptable letter of the 9th of July with the accompanying books I received only last week, while at Liverpool, at the very meeting you refer to and I heartily wish that you had been there yourself. It is now five years since I have been able to attend any of these meetings but I was very pleased with the one to which I now refer. . . . As the Association forms no collection of books or apparatus I gave the said copy of your work to Professor Henry of Philadelphia in the United States with a view of extending what you have done as far and as fast as possible and wherever the English language is found. He was exceedingly obliged to me for it and I only wish that you and he had met at Liverpool. . . ."

"With regard to Mr. Croese's insects, etc., I do not think anybody believes in them here except perhaps himself and the mass of wonder-lovers.—I was said in the English papers to have proved the truth of his statement, but I immediately contradicted the matter publicly. . . . It is but just of me to say that in conversation with Mr. Croese I was very much pleased with him and with the readiness with which he received my critical remarks. As regards the crystallization supposed as real, he was lugged into view and must not be charged with having pressed himself forward. He is in fact a very modest man but has been dragged into an unkind situation. . . ."

David Uwins (1780–1837)

DR. DAVID UWINS, one of the first English converts to homœopathy, was born in London in 1780, the son of Thomas Uwins, a clerk in the Bank of England and brother of Thomas Uwins, the artist. He received his medical training in London and then went to Edinburgh, where he graduated M.D. in 1803. He then returned to London, where he was made L.R.C.P. in 1807. In 1815 he was appointed physician to the City Dispensary and afterwards to the Finsbury and Central Dispensary. In 1828 he became physician to the lunatic asylum at Peckham, and as the result of his experience in that institution published in 1833 "A Treatise on those Disorders of the Brain and Nervous System called Mental". In later life, owing to the influence of his friend Frederick Hervey Quin, he took up homœopathy, and in 1836 announced his conversion to that doctrine in a pamphlet entitled "Homœopathy and Allopathy, or Large, Small and Atomic Doses". As the result of this step he quarrelled with his former friends and his health broke down owing to the stress of controversy. He died in London on September 22, 1837, and was buried in Kensal Green Cemetery.

Uwins was a prolific writer. In addition to the works already mentioned his chief publications were "Modern Medicine, containing a Brief Exposition of the Principal Discoveries and Doctrines" (1808), "A Compendium of Theoretical and Practical Medicine" (1825) and "A Treatise on those Diseases which are either directly or indirectly connected with Indigestion, and on the Principal Ailments of Children" (1827). He also contributed medical articles to Gregory's "Encyclopædia" and the *Quarterly Review*, and was for some time editor of the *Medical Repository*.

Lyell to Leonard Horner

LYELL had spent the months June to September 1837 on the Continent and thus had not been able to attend the British Association meeting at Liverpool. Just before he returned home he wrote on September 23 from Paris to Leonard Horner (1785–1864), the geologist, "I am glad to receive your report of the meeting at Liverpool, and to hear the Association was so well supported. I must try to be at the next. I saw a very blundering account of my letter in the 'Athenæum'. I am anxious that when printed by the Association, it should be given as I sent it, and this principally because I have carefully avoided bringing prominently forward any collision with Von Buch, whom I like too well not to be sorry that he should fancy, as he has done before now, that I am always seeking to run against him. I only mentioned him as having been the first to announce the posteriority of the granite to the transition beds, which was a grand step at that time, and true; though perhaps he did not come at it by a strictly logical course. I knew how he drew his inferences, which were quite natural twenty-six years ago, before he had adopted the true theory of granite, but had I brought forward his errors, I should also have dwelt on his praises. Chancellor Brougham said of Serjeant Wilde, that it was rather hard to visit on the barrister the sins which he committed in the flesh as an attorney, and I should also think it hard to show up the mistakes which Von Buch the Huttonian fell into, in the youthful days of his Wernerianism."

Societies and Academies

Paris

Academy of Sciences, July 12 (*C.R.*, 205, 97-184).

ANTON E. MAYER: Groups of curves of three lines.

MME. CHRISTIANE PAUC: Further study of a group of infinitesimal transformations.

JACOB: Determination of the jump of a function by development in a Hermitian series.

CHI-TAI CHUANG: The behaviour of a holomorphic function and of its derivatives in a circle.

PIERRE CHEVENEARD and EUGÈNE JOUMER: A mechanical magnifier with enlargement of more than 1,000. Application to recording the viscous deformation of metals at high temperatures.

MAX SERRUYS: Supplements to the nuclear inflammation theory of knocking in petrol motors.

F. J. BOURELIER: The auto-oscillations of real jets in identical media by autofolds.

ALBERT MILHOUD: Concerning the inflammation of dirigible balloons. Discussion of the conditions producing an electric spark when the valve is opened to allow the hydrogen to escape.

ROGER MÉRIGOUX: The influence of a thin layer of oil on the motion of waves.

MARCEL PAUTENBERG, MOSHÉ FELDENEKRAIS and LÉOPOLD VIGNERON: The absolute standardization of an apparatus for the measurement of very high voltages: the electrostatic valve. The indications of the rotating voltmeter standardized up to 50 kilovolts are in agreement with the results given by the electrostatic valve method, up to about 400 kilovolts.

THADÉUSZ PRZYSŁSKI: The production by electrolysis of coloured rings in the mass of a salt.

HENRI LACOSTE-TAYAN: Cycles of recoil in magnet steels.

SERGE NIKITINE: The dichroism of flow in solutions of fluoresceine.

LOUIS CARTAN: The focalization of corpuscular bundles by circular deviation in a transverse magnetic field.

MAURICE COTTE: The Gauss approximation for the general systems of electronic optics.

RAYMOND ROURE, LOUIS QUEVRON and RENÉ GENES: A photo-electric comparator. The instrument reduces the measurement of a variation of length to the measurement of a variation of current. A displacement of 1 micron produces a change of 0.4 milliamperes.

RENÉ AUDUBERT: The ultra-violet emission spectrum of the slow thermal dissociation of silver nitride. The slow decomposition of silver nitride by heat is accompanied by the emission of light, corresponding to three narrow bands between 1950 Å. and 2600 Å.

EMILE RINCK: The diagram of solidification and electrical conductivity of the rubidium-caesium alloys. These two metals form a continuous series of solid solutions, with a minimum solidification point at 9° C. The conductivity measurements proved that no definite compound of caesium and rubidium is formed. These results are not in agreement with the earlier work of Gorla on the same subject.

MAURICE DODÉ: The reversible action of iodine vapour on dry potassium nitrite. The influence of the miscibility of this salt with the corresponding nitrate.

CLÉMENT COURTÉ: The diamagnetism of solutions of iodine and the purity of the alcohol. The law of additivity of coefficients of magnetization applies to a solution of iodine in alcohol only if the latter is pure, and such measurements can be used for detecting the presence of impurities in alcohol.

ANDRÉ DEBIÈRE: A new mode of transformation. When hydrogen is brought into contact with purified carbon at the temperature of liquid nitrogen a large amount of heat is set free, higher than the heat of combustion of the hydrogen with oxygen. Helium shows a heat evolution of the same order of magnitude under the same conditions, but with other gases (oxygen, nitrogen, argon) the effect is small. The source of this heat energy is unknown.

MARCO TIFFENHAU, PAUL WHITE and BIANCA TOHOUBAR: The order of addition of the hydrides to the epoxides and of the hypohalogen acids to the ethylene derivatives, methylene cyclohexane and methylcyclohexene, as well as their epoxides.

RAYMOND QUELET and MARCEL PATY: New methods of preparation of 5-bromo-2-methoxybenzyl alcohol and of 5-bromo-2-methoxybenzaldehyde.

ANDRÉ MEYER and HENRI DEUTEL: The 2,6- and 2,8-dimethyl-4-chloroquinolines. General properties. The reactions with amines.

HENRY GAULT and MATIAS COGAN: Ethylol-formylglutamic ester.

ALEXIS TCHITCHIBABINE and CHARLES HOFFMANN: A new (2,3,6) triaminopyridine.

LOUIS MARTINHAU and CHARLES PRÉVOST: The catalytic dehydrogenation of a tertiary alcohol into a ketone.

LUCIEN DAUTERBANDE, EDMOND DUMOULIN and PIERRE ANGNOT: Study of anti-aerosol esparto pulp filters. The perforation of anti-aerosol filters by the ageing test with steam.

PIERRE LEGOUX: The magnesian series of supracrustal rocks of the west Ivory Coast.

JULIEN DURAND: The structure of the crystalline region of Rouergue and of Albigeois.

PIERRE BERNARD: The relation between the swell on the coast of Morocco and the microseismic agitation in western Europe.

EDMOND ROTHÉ and TH. KOPONWICZ: The comparison of the radioactivity of Alsatian rocks by the method of (Geiger-Müller) counters.

ALBERT BALDIT: The influence of the terrestrial relief on the vertical movements of the air at Bannet-d'Ordanche (Massif of Mont-Dore). Studies of air velocities made in connexion with a school for gliding.

RENÉ SOULES: The embryogeny of the Violaceae. The development of the embryo in *Viola tricolor*.

LUCIEN LEBOUX: The presence of allantoinic acid in the leaves of *Corylus avellana*.

VINCENT, HERVIAUX and COIC: The measurement of the lime capacity of soils, and the liming of acid soils.

JEAN JACQUES BOURHIOL: Premature metamorphosis by the ablation of the *corpora allata* in the young silkworm.

JULES ALQUIER and MME. ANDRÉE MICHAUX: Study of the calcium-phosphorus ratio in various tissues especially in the femurs of the growing rabbit.

JEAN LAVOLLAY and MME. FRANÇOISE LABORY: The action of ascorbic acid (vitamin C) on the pigmentation of the mycelium of *Aspergillus niger* in the presence of magnesium in excess, and on the development of this mould.

RODOLPHE L. MAYER and CHARLES ORCHSLIN: Antistreptococci. Extract from a sealed letter on the activity and toxicity of certain derivatives of benzene sulphamide.

EMILE ROUBAUD, JACQUES COLAS-BELOOUR and GEORGES JEAN STEFANOPOULO: The transmission of yellow fever by a palaeartetic mosquito common in the Paris region.

Moscow

Academy of Sciences (C.R., 15, No. 4, 1937).

V. S. IGNATOVSKIY: The Laplacean transformation (7).

G. V. PREIFFER: Possibility of joining to a complete system of non-linear equations a linear equation or a system of linear equations.

B. LEWITAN: A generalization of inequalities of S. Bernstein and H. Bohr.

G. N. NEUMIN: The elements of the orbit of Comet 'Neujmin II' as computed from the connexion between its appearance in 1916 and 1927.

B. J. SYVINSKOV: Dependence of the rate of photo-chemical reactions in solution on the concentration of reagents.

V. SUKACHEV and S. DOLGAJA: Fossil remains of plants in loess and loess-like clays in connexion with the problem of origin of these deposits.

K. A. VLASOV: The theory of desilification of granitic pegmatites.

E. S. BUKSEER, N. P. KAPUSTIN and V. V. KONDOGUBY: Helium, radium and thorium in beryllium minerals of the U.S.S.R.

D. MICHLIN and P. KOLMENIKOV: Influence of colloids and of electrolytes on the state of equilibrium in maltose.

D. J. VAKOLIN: Some data on the yield of essential oil by a new variety of dragonhead (*Dracocephalum moldavica* L. var. *hexagonum* D. Vakulin) from different seed samples.

E. M. SEMPIL'VA: Morphology of the chromosomes of some species of potato.

B. S. MOŠKOV: Photo-periodism and a hypothesis as to flowering hormones.

M. CH. ČAJLAČAN and L. M. YARKUVAYA: New facts in support of the hormonal theory of plain development (2).

A. R. VERNER and V. F. ALTNRGOT: The phenomenon of mycophagy.

Sydney

Royal Society of New South Wales, July 7.

ADOLPH BOLLIGER: Red compounds formed by picric acid and creatinine in the presence of sodium hydroxide. Four compounds have been isolated. They are characterized by a varying sodium or sodium hydroxide content. Compound I, which is obtained *inter alia* by the addition of one molecule of sodium hydroxide to a mixture of one molecule of creatinine sodium hydroxide and one molecule of picric acid, consists of one molecule of creatinine, one of picric acid and two of sodium hydroxide. Compounds II, III and IV, obtained after the addition of larger amounts of sodium hydroxide, contain two and a half, three and three and a half molecules of sodium hydroxide for each molecule of creatinine picrate. Compound IV represents the maximum degree of saturation with sodium hydroxide and has been considered as the most likely cause of Jeffe's reaction.

Vienna

Academy of Sciences, June 24

E. STEINACH and H. KUN: Conversion of the male sex hormone into a substance with the properties of the female sex hormone. Studies with young and old men. Injection of male sex hormone produces in the urine a substance with oestrogenic properties.

J. SCHINTELMISTEER: Redetermination of the range of α -particles from thorium. The variation of the ionization along the range of the α -particles from a thorium source of exceptional purity has been studied, and the extrapolated and mean ranges in air at 0° C. and 760 mm. pressure have been determined as 2.59 cm. and 2.56 cm. respectively.

R. WEISS: 4', 4''-dihydroxy-3', 5', 3'', 5''-tetrabromonaphthalene-2, 3-dicarboxylic acid anhydride.

O. REDLICH, T. KURZ and W. STRICKS: Spectrum of scattered light of some inorganic compounds.

BELLA BAUMINGER and F. LIEBEN: The sugar-formic acid combination in the oxygen current.

Washington, D.C.

National Academy of Sciences (Proc., 23, 295-349, June 15).

D. L. FOX: Carotenoids and other lipid-soluble pigments in the sea and in deep marine mud. Material filtered from sea water, including microplankton, faecal matter and other organic detritus, and also marine muds from 1,000 fathoms were found by chromatographic analysis to contain carotenoids, assuring a supply of these compounds even to deep-sea animal organisms.

H. D. BARCOCK: Internuclear distance in oxygen molecules. New determination based on measurements of twelve absorption bands of atmospheric oxygen.

J. M. BEAL: Bud development in *Lilium Harrisii* following treatment with indoleacetic acid. In another species, treatment with this substance in lanoline of a stem from which the terminal bud had been removed produced protuberances found to be adventitious roots; in *L. Harrisii* buds appeared in the axils of the upper two or three leaves. These buds closely resemble bulbils (vegetative reproductive organs) normally found near the base of the stem.

S. WRIGHT: The distribution of gene frequencies in populations. A mathematical discussion.

H. FRICKEN and M. DEMEREC: The influence of wave-length on genetic effects of X-rays. Wave-lengths of 0.94 Å. and 2.2 Å. were used. *Drosophila melanogaster* males were treated individually in a chamber in which their abdomens were compressed to a thickness of about 0.15 mm. in order to reduce absorption of this soft radiation. The frequency of lethals per unit dose is found to be the same for both wave-lengths, suggesting that the genetic changes are not due to direct activations within a gene but are probably of the nature of sensitized reactions induced by neighbouring activated molecules.

M. E. REISSNER: Theory of beams resting on a yielding foundation. A mathematical discussion, from which it is claimed that, provided the deflection of the surface of the foundation due to a concentrated loading is known, then the problem of buckling of a beam of infinite length, resting on a yielding foundation and on an infinity of equidistant supports, can be solved completely.

G. A. MILLER: Groups having a maximum number of independent generators.

E. KASNER: Trihornometry: a new chapter of conformal geometry. A trihorn is defined as an ordered triplet of curves which pass through a common point in a common direction. Various relationships between the conformal invariants of this configuration are derived, including the analogues of the laws of sines and cosines of ordinary trigonometry.

J. v. NEUMANN: Continuous rings and their arithmetics.

Forthcoming Events

INSTITUTE OF SOCIOLOGY, September 24-26.—Conference on "Social Stratification and Class Conflict" to be held at King's College of Household and Social Science, Campden Hill Road, W.8.

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX, September 24-27.—Annual Conference to be held at Gonville and Caius, Cambridge.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.

LABORATORY ATTENDANT in the Science Department, South-East Essex Technical College, Dagenham—Clerk to the Governors (September 25).

LECTURER IN BIOLOGY in the Kingston-upon-Thames Technical College—The Principal (September 25).

HEADMASTER of the Bagdad Technical School—The Secretary (I.P.R./O.A.), Board of Education, Whitehall, S.W.1 (September 30).

TWO INSPECTORS FOR THE DEPARTMENT OF AGRICULTURE FOR SCOTLAND—Secretary (Establishment Branch), Department of Agriculture for Scotland, 29 St. Andrew Square, Edinburgh 2 (September 30).

ASSISTANT EXECUTIVE ENGINEER in the Public Works Department (Irrigation Branch) of the Government of the Punjab—High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (October 1).

ASSISTANT LECTURER IN MUNICIPAL ENGINEERING in the Manchester Municipal College of Technology—Registrar (October 4).

CHIEF LECTURER IN HISTORICAL ENGINEERING in the West Ham Municipal Technical College—The Principal (October 9).

ENGINEER SUB-LIEUTENANT in the Royal Indian Navy—Secretary, Military Department, India Office, London, S.W.1, marked "Engineer Recruitment" (October 18).

ASSISTANT LECTURER IN MATHEMATICS in the University of Manchester—Registrar.

ENGINEER in the Public Works Department of the Government of Sarawak—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quote M. 5419).

LECTURER IN PHYSICS in the University of Reading—The Registrar.

Official Publications Received

Great Britain and Ireland

Technical Publications of the International Tin Research and Development Council. Series A, No. 57: Mechanical Properties of some White-Bearing Metals and other Tin-Base Alloys at various Temperatures. By Dr. O. B. Homer and H. Plummer. Pp. 20+4 plates. Free. Series A, No. 58: The Tensile Properties of a Series of White-Metal Bearing Alloys at Elevated Temperatures. By H. Greenwood. Pp. 9. Free. (London: International Tin Research and Development Council.) [258]

Scottish Society for Research in Plant-Breeding. Report by the Director of Research to the Annual General Meeting, 22nd July 1937. Pp. 29. (Edinburgh: Scottish Society for Research in Plant-Breeding.) [268]

Norman Lockyer Observatory. Director's Annual Report, April 1, 1936-March 31, 1937. Pp. 6. Council's Report and Accounts and List of Council, Staff, Members, etc., June 1937. Pp. 12. (Bristol: Norman Lockyer Observatory.) [268]

Readers' Guide to Books on Electrical Engineering. Pp. hi+16. (London: Library Association.) [268]

London Shellac Research Bureau. Technical Paper No. 11: Viscosity of Lac and Hard Lac Resin Solutions. By Dr. Lal C. Verma. Pp. 20. Technical Paper No. 12: Modification of Lac with Higher Fatty Acids and their Mixed Glycerol Esters, Part I. By Dr. R. Bhattacharya. Pp. 16. (London: London Shellac Research Bureau.) [268]

Department of Scientific and Industrial Research. Report of Test by the Director of Fuel Research on the Plant of the National Coke and Oil Company, Ltd., at Brith, Kent; Tests carried out 26th January to 9th February 1937. Pp. vi+54+2 plates. (London: H.M. Stationery Office.) 1s. net. [29]

Proceedings of the Royal Irish Academy. Vol. 43, Section B, No. 5: Turbellaria of Ireland. By Bowland Southern. Pp. 43-72. 1s. Vol. 43, Section B, No. 11: River Liffey Survey—The Ostronomid Fauna of the Submerged Mosses. By Carmel F. Humphries and Winifred H. Frost. Pp. 161-181. 1s. 6d. (Dublin: Hodges, Figgis and Co.; London: Williams and Norgate, Ltd.) [29]

St. John Cass Technical Institute. Calendar, Session 1937-1938. Pp. 141+3 plates. (London: Cass Technical Institute.) [29]

The Prediction and Reduction of Occultations. (Supplement to the Nautical Almanac for 1938.) Pp. v+46. (London: H.M. Stationery Office.) 2s. net. [29]

Department of Scientific and Industrial Research. Index to the Literature of Food Investigation. Vol. 7, No. 1, March 1935. Compiled by Agnes Elizabeth Glemie, assisted by Gwen Davies. Pp. xii+371. (London: H.M. Stationery Office.) 5s. net. [29]

The Organization of Social Research

EVERY year the social services of Great Britain tend to attract increased attention and generally to demand increased expenditure of public money. This may be all to the good ; but from time to time it is desirable to attempt to survey the situation and to consider whether in practice these services are being adequately directed by controlled and informed social research. In a field of this kind, where the boundaries are extremely wide and the claims in every direction are most insistent, constant and wise research is particularly necessary if undue waste is to be avoided and if merely sectional interests are to be held in reasonable control.

As things are at present, our problems of public health have been placed upon a sound foundation, mainly through the organization and activities of the Ministry of Health and later of the Medical Research Council. Research in agriculture is now being similarly promoted by the more recently established Agricultural Research Council. The National Physical Laboratory and the Department of Scientific and Industrial Research, likewise subsidized by the State, have brilliantly developed the contributions which can be made by physics and chemistry to a great variety of industrial and even social problems. The Industrial Health Research Board, with far more slender resources and with a less independent status, has made valuable contributions to some of the problems of industrial life. So far as national organization goes, that is all. Other problems—economic, educational, biological, psychological, sociological—are left to advisory or to consultative committees, which can receive 'evidence' and issue reports (but do little else), or to private enterprise and sporadic effort.

It is high time to alter this state of affairs—to establish a new scientific body, with adequate endowment from the State, which will do for human social research what the Medical Research Council does for public health, what the Agricultural Research Council is beginning to do for agriculture, and what the Department of Scientific and Industrial Research does for the applications of physics and chemistry. Such a body must be nationally constituted ; for most of the problems which it would be asked to study are the immediate and practical concern of existing government departments.

Everywhere, and in all directions, the most prodigious efforts are now being made to bring differently organized social groups into peaceful and lasting co-operation. But we have much yet to learn about the nature and extent of these differences ; for example, of class-differences and of class-conflicts. In industry, in education, in politics national and international, in science, and in religion, it is essential that bases of successful co-operation be found—or the world as we know it must disappear in faction, enmity and confusion.

Scientific invention and popular education have combined to bring groups widely different in language, or tradition, or custom, or aim, or, all of these, into close contact ; and every day potentialities of conflict threaten to become actual or even to break into sharp strife producing lasting irritation and lamentable waste. Many of the best minds are set to devise all manner of elaborate machinery for promoting and preserving friendly relations between groups. Yet if but a fraction of the intelligence that has been put to work upon this problem of machinery had been devoted to a study of those human conditions

which will inevitably wreck even the most wisely devised machinery, there would have been great economy and far more to show for the effort. The methods for a controlled study of the bases of group co-operation—and of consequent government by consent—are to hand. They can be made as scientific and as definite as those of the investigation of any other human problem. They require wide application, for which centrally and nationally organized effort is necessary.

It is clear that at the present day the great mass of the work of the world can be performed efficiently with a relatively slender equipment of intelligence, and—what is probably more important still—with only a small basis of acquired knowledge. This is due to the enormous advances of physical science and especially to the modern applications of engineering. The great requirement now, so far as the working-day activity of the masses goes, is for specialized skills, not for extensive knowledge. Moreover, the time during which these specialized skills must be kept continually in operation in order that the basic needs of civilization may be satisfied is all the while decreasing. We may even say, with an approximation to truth, that, apart from the institutions devoted to technical training, modern popular education is now designed mainly for leisure, not for work.

We know, however, extraordinarily little of how, if at all, the majority of workers in any section of a modern community utilize their education for their leisure, and even less about how and how wisely leisure occupations are chosen and how they affect social and workaday behaviour. There can be no doubt that the views, opinions and beliefs which influence public policy in many directions are stimulated and developed chiefly during periods of leisure. Consequently, the most stable community in modern social life appears likely to be the one in which leisure is ample and most ably employed; and as science still further advances its techniques, the truth of this will become even more obvious. It is not, therefore, surprising that serious attention is at length being given to stimulating the study of leisure and of its influence in human affairs; but this study needs adequate control and organization.

Bound up with the increasing importance of leisure is the fact that leisure has itself become possible largely as a result of a great speeding-up in the *tempo* of work and in the specialization of routine processes. There is a general impression

that these two conditions—speeding-up and increase of routine—are exerting profound influences upon human behaviour and consequently upon social policy. They may be responsible for special occupational difficulties or disorders, the study of which overlaps the field of medical research. They may give rise to a degree of dissatisfaction which inevitably results in various forms of group conflict. They may encourage individual maladjustments to an extent which has wide repercussions upon family and social life. Whether or no they do these things, in what directions, how and when, are all matters for speculation at the present time; but they could be made matters of far more certain knowledge.

The general drift of social development for many years past seems to have been for more and more of the functions which were formerly those of small groups to become the direct practical concern of larger ones. Thus the functions of the family—so often in a vague way said to be disastrously breaking down—in regard to education, health, industrial training, and many everyday regulations of behaviour, have passed largely to some wider authority constituted within the nation-group. Similarly, the functions of local religious, industrial and general administrative groups have in many instances been lost or become strictly controlled. Coincidentally, human loyalties, partly by training and propaganda, partly by natural drift, seem to have been diverted from the smaller to the larger groups, or to have changed in character as regards the smaller groups. On one hand, any more forcible and competent social group must be able to perform functions on behalf of its members better than any smaller, less organized group can do; and on the other hand, every large modern society, such as the nation-group, must necessarily contain and maintain in very great variety internal social differentiation. A study, therefore, by experimental and observational methods, of the place and functions of small groups in a large society, would have a close bearing upon many urgent problems of practical social control.

These are a few only of a large number of other general problems (for example, those of population and of crime) upon the solution of which the effectiveness and stability of present and future social organization depend. They are matters of daily debate and speculation; and in that stage they will remain, unless they are conceived, as they properly should be, as problems in higher human biology, to be attacked, not by dialectic

alone, but by experiment when possible and by controlled observation. Methods for such an attack are already being devised and applied. But they will have little chance of success, unless they can attract the attention of, and be refined and sharpened by, the best scientifically trained minds available.

Besides these general problems, there is a mass of more specialized questions which call for immediate and organized research. Much brilliant recent physiological investigation, on 'conditioning', on habituation, on adaptation, on inhibition and on the development of co-ordinated motor activity, has its most significant application to human behaviour. The last ten years have seen the study of the operation of incentives and 'drives' placed upon a much firmer basis in so far as the behaviour of animals is concerned; but virtually nothing is known, except in a speculative sense, about their conditions and mode of operation in human society. Modern civilization depends to a considerable extent upon skills of one kind and another, yet we are only at the outset of ascertaining the principles which determine how different skills can best be acquired and maintained. In region after region, throughout the British Empire, wherever native populations are being rapidly caught up in modern Western ways of life, urgent practical difficulties concerning education, administration, and the swift transformation of manners and customs arise and cannot be postponed. As things are, the administrator is forced to do his best to meet such problems *ad hoc*, and in a hurry. There are principles underlying the correct solution of them

all; but these principles demand organized research for their discovery, and hitherto the State has given no systematic support for such research.

Indeed, at the present time in Great Britain, if a government department, or any outside person or body, is brought up against some research problem underlying the administration of any branch of the social services, there is little that can be done beyond referring it to the Medical Research Council or to an advisory committee. This is scarcely fair. The Medical Research Council is usually sympathetic; but many of the problems thus proffered are remote from its terms of reference, and in any event its resources are insufficient to do much more than meet its own immediate concern with public health in the specifically medical sense of the phrase. Also, though an advisory committee can inquire into whatever research may be in progress and can collect opinions, it cannot initiate original investigations on an adequate scale.

A new, centrally constituted scientific body is urgently needed, to survey the field of social research and to set on foot considered programmes of actual investigation on higher biological lines. The questions demanding study are most of them border-line problems, at the growing points of research in different departments of science, involving organized and many-sided efforts for their solution. There is no government department that could not profit vastly from such an enterprise. Ultimately the public purse would be saved from much wasteful expenditure, and the country's social services set upon a firmer foundation of well-attested knowledge.

Exploration in Iran

Archæological Reconnaissances in North-Western India and South-Eastern Iran

Carried out and recorded with the support of Harvard University and the British Museum by Sir Aurel Stein. Antiques examined and described with the assistance of Fred H. Andrews and analysed in an Appendix by R. L. Hobson. Pp. xx + 267 + 60 plates. (London: Macmillan and Co., Ltd., 1937.) 63s. net.

AFTER forty years of research and exploration in and around Central Asia, Sir Aurel Stein found himself constrained by the intolerable character of the conditions imposed on his activities

by the Chinese Government to cease from further investigation in a field which he had regarded as the major objective of his studies. While he has every sympathy in his personal disappointment and frustration when the expedition in Inner Mongolia was abandoned, the loss to science by the diversion of his experience and knowledge to other regions is felt to be a calamity. Nevertheless, there is compensation of a kind in the fact that by an arrangement with Harvard University and the British Museum, which were his sponsors, he was able to turn to the exploration of regions of the Middle East, which were still archæologically unexplored and geographically imperfectly known.

By October 1931, Sir Aurel's arrangements for the first of his journeys in southern Iran were complete, excepting for the official permit to travel in Persia. Pending its receipt, which was delayed until the end of the year, Sir Aurel revisited the northern Punjab and the Salt Hills, where he began his career as a field archaeologist in 1889. The purpose of this interlude was to round off his studies of the invasion of India by Alexander the Great by examining the scene of the last phase of that adventure at the point where the invading forces turned back, and to determine the exact spot at which the defeat of Poros on the banks of the Hydaspes (Jhēlum) took place, a problem of which, after prolonged examination of previous theory on the ground, he concludes that a final and exact solution is improbable. In the account of his present journey in the Salt Hills, he includes the first full statement to appear, after nearly fifty years, of the detailed topographical and archaeological argument by which he identified the Jain temple mentioned by the early Chinese Buddhist traveller Hsüan-tsang, and the site of the ancient Simhapura.

Early in January 1932, Sir Aurel left India for Makrān; and a few days later he crossed the frontier from the British post at Suntsar, and began under escort his long journey through Persian Makrān and Baluchistan to Kermān, where the advancing season, too hot for further archaeological exploration, brought his first journey to a close. Re-assembling his party after he himself had spent a brief period in England, he set out from Kermān in October 1932, his purpose being to explore the coast of the Persian Gulf in search for early historic and prehistoric sites. He travelled south to Mināb at the mouth of the Persian Gulf and thence proceeded along the inhospitable coast; but before his journey as planned was completed, all further exploration was forbidden by the Persian authorities owing to tribal unrest, and his second journey came to an end at Bushire.

In the two journeys of the period 1931-33, Sir Aurel had covered two thousand four hundred miles of country, almost the whole of which was, for archaeological studies, virgin territory. Of this he had also made a topographical survey, except for an interruption of his observations for a time by the officious, and as it proved, unauthorized veto of the commander of his escort. The course of his journeys was determined by archaeological 'points', the occurrence of burial mounds and occupation sites of prehistoric or early historic age. It is to be noted that though historic sites were found along the actual coast line, there was none here of prehistoric age, a fact of which Sir Aurel discusses the significance and suggests that it may be due to submergence.

A large number of sites, both of prehistoric and early historic age, were examined and recorded. Time was not available for an intensive study of any one site, and there are several on which the author insists upon the urgent necessity for systematic and exhaustive excavation. It was possible, however, by surface finds and trial trenches to collect and determine the sequence of a large quantity of ceramic evidence and other material—stone and bone, copper, bronze, iron and glass (beads and bangles)—in date extending from the chalcolithic age down to the close of the pre-Islamic period, several centuries after the commencement of our era. An idea of the richness of some of the sites in archaeological data may be gathered from the fact that at Damba-kōh, a hillock-site in the alluvial plain of the Bāhū river, about sixteen miles only from the frontier, there were at a rough estimate seventeen hundred cairn burials, or if those scattered nearby are taken into the account, some two thousand. The practice of cairn burial shows a considerable variety in construction, but the skeletal remains are invariably those of bodies which have been exposed previously to burial. In this area, the author infers, it must have persisted for a very considerable period, extending from the close of the pre-Islamic period back to, at least, the Iron Age.

On the prehistoric or chalcolithic sites there is abundant evidence, in the painted pottery in particular, of affinity on one side with the chalcolithic civilization traced by Sir Aurel on his expeditions to Baluchistan in 1926-28, which in turn links up with the civilization of the Indus valley, and on the other, with early western Asia. Finds from the Tal-i-pir (Haraj), for example, especially the painted pottery and the 'button-seals', are compared with those found at Persepolis, Arpachiyah and Fars. Further, the designs in monotone of the yellowish-grey ware from this site provide a link between Persepolis and the chalcolithic site at Fars and Baluchistan, where most of the designs appear, while the bands of horns found here as a form of decoration relate Baluchistan, Iran and Susa.

Sir Aurel has modestly given to this elaborately produced and detailed account of his first two journeys in Iran the title of 'Reconnaissances'; and so these journeys must be regarded, as providing both a strong incentive and guidance for further and more intensive archaeological investigation—this not only for its own sake, but also for the light it will throw on the relations of early civilizations in India and Mesopotamia. At the same time, the topographical and archaeological record, as well as the magnificent series of plates of the pottery and other finds, ensure its permanent standing as an authoritative work of reference.

Men and Mathematicians

Men of Mathematics

By Prof. E. T. Bell. Pp. 653. (London: Victor Gollancz, Ltd., 1937.) 12s. 6d. net.

PROF. E. T. BELL has written a fascinating book. The amount of biographical details and of mathematics that he has compressed into a volume of 650 pages is extraordinary; but he is never dull; his style is lively, at times even 'snappy'; he carries the reader along; he whets the appetite. No doubt the mathematician of a certain age who remembers little more mathematics than what he learnt at school and at the university will wish that the modern theories and developments could be more fully described so that he could get a better general idea of them; and the reader who is mainly interested in the personal and human side, while reading with enjoyment the biographical details, which are not easily accessible elsewhere, will wish for more. This is as it should be; but, if the writer has set himself what is (in such a compass) a wellnigh impossible task, we are not the less grateful to him.

Prof. Bell explains that he has applied two criteria in selecting names for inclusion: first, the importance for modern mathematics of a man's work, and, secondly, the human appeal of the man's life and character. Some, as he says, qualify under both heads, for example, Pascal, Abel and Galois; others, like Gauss and Cayley, chiefly under the first, though both had interesting lives. When the two criteria clash or overlap as between several claimants for inclusion on account of a particular advance, he has given the second the precedence, as his primary interest is here in mathematicians as human beings.

In his first chapter Prof. Bell deals with the Greeks—Zeno, Eudoxus and Archimedes; then, with a bound over eighteen centuries, he passes to Descartes and Fermat, the founders of analytical geometry. This is because, throughout the book, "the emphasis is wholly on modern mathematics, that is to say, those great and simple guiding ideas of mathematical thought that are still of vital importance in living creative science and mathematics". The particular Greeks dealt with are those whose work makes, as it were, a continuous story with that of the moderns. The story properly begins with Zeno of Elea. Zeno did not indeed claim to be a mathematician, and next to nothing is known of his life; but he put forward the four famous paradoxes which have exercised the acutest minds ever since, and even now, notwithstanding the labours of Weierstrass, Dedekind and Georg Cantor, cannot be said to be disposed of finally.

Though some of the great mathematicians were born in the humbler walks of life, they are not in a majority. Monge was the son of a pedlar and knife-grinder, Fourier of a tailor, Fermat of a leather-seller; Gauss's father worked as a gardener, canal-tender and bricklayer. Laplace was the son of a peasant and became a 'complete snob'; he examined Napoleon as a candidate for the Military School, and afterwards, in recognition, Napoleon 'pushed' him in every possible way; he was Minister of the Interior for six weeks; under Louis XVIII he sat as Marquis de Laplace in the chamber of peers. Most of the others were sons of professional men, chiefly in the law, officials, pastors, and so on. Some were miserably poor or became so; Kummer tramping back and forth every day between Sorau and Halle with his food and books in a knapsack on his back reminds us of Eudoxus trudging from the Piræus to Athens and back to hear the lectures of Plato.

Only a few of the subjects of the book seem to have been exceptionally precocious. Though the legends of Pascal's precocity are no doubt overdrawn, he discovered his famous theorem before reaching the age of sixteen years. Lagrange is said to have become professor of mathematics at the Royal Artillery School in Turin at sixteen years of age. Gauss, before he was three years old, spoke up and corrected an error which his father had made in calculating the weekly wages of some labourers; in his tenth year he produced in a few seconds the answer to an addition sum set to his class, in which a hundred numbers beginning with 81,297 and ending with 100,899 were to be added, because he instantly saw that the numbers formed an arithmetical progression with 198 as common difference. Sir William Rowan Hamilton must almost have rivalled John Stuart Mill: he was a good reader and advanced in arithmetic at three years of age; at five he read and translated Latin, Greek and Hebrew; at eight he added Italian and French and wrote an original poem in Latin hexameters. Euler ("analysis incarnate") was, like Gauss, a marvellous calculator. Two of his students summed a complicated convergent series in specific numbers and disagreed only by a unit in the fiftieth place of the result. To decide between them Euler did the whole calculation in his head; his answer was found to be correct.

Prof. Bell has strong likes and dislikes. He cannot forgive Newton for accepting, at the age of fifty-four years, the post of Warden of the Mint, nor Leibniz for spending so much of his life in the trivial service of the Brunswick family.

Citrus Diseases

Citrus Diseases and their Control:

By Prof. Howard S. Fawcett. (McGraw-Hill Publications in the Agricultural and Botanical Sciences.) Second edition, completely revised, rewritten and enlarged. Pp. xv + 656. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 36s.

A SECOND edition, after ten years, by the senior author of Fawcett and Lee's well-known book must be welcome to a great industry and to citrus pathologists. Lee, being engaged on other investigational work during recent years, generously withdrew from joint authorship of the new edition. The arrangement of the matter is the same as in the first edition, but with fifty-three additional pages of text (apart from the bibliography) and two new chapters. Significant of the notable extension of citrus planting outside of the United States during late years and the attention given by trained pathologists to the diseases and means of control, is the expansion of the chapter on the geographical distribution of citrus diseases from six to thirty pages.

A new chapter has been added on 'diseases due to deficiency or excess of inorganic constituents' in collaboration with Haas of California, and the parts treating of sweet orange and Australian scab and of citrus blight have been written with the help of Miss Jenkins of Washington and Rhoads of Florida respectively. Descriptions are given of about a score of diseases either not mentioned at all or only cursorily dealt with in the first edition; among these *Mal Secco*, a specific disease as understood now (due to *Deuterophoma tracheiphila* Petri), and of serious moment in the lemon plantations of eastern Sicily, is probably the most out-

standing. Of the diseases fully treated in the first edition, Fawcett now records that no cases of canker (caused by *Bacterium citri* (Haase) Doidge) have been detected in Florida since 1927, and that it appears to have been eradicated from all commercial plantings in the other Gulf States. The great campaign aiming at the total eradication of canker, begun in Florida in 1914 and extended to the neighbouring States, seems, therefore, to have been wholly successful: it has cost about two and a half million dollars. A similar campaign of eradication against canker in the Union of South Africa, begun in 1918, has been equally successful. These two effective campaigns against a highly infectious disease (the very susceptible grapefruit was the variety mainly concerned), seem destined to become classical in the history of plant disease control.

The author presents strong evidence, based mainly upon his own investigations, in support of the view that psorosis, a disease of wide distribution, the etiology of which baffled pathologists for many years, is due to a virus.

The bibliography has been enlarged from seventeen to forty-one pages, due in part to the filling of gaps in the references recorded in the first edition and to the very complete list of those of the last ten years (to the end of 1935).

The make-up of the book corresponds with the high standard of the first edition; the plates in colour, remarkable products of the technique of reproduction, are the same as those in the earlier edition. Should the new edition be reprinted, it would seem an added convenience if the plates could be numbered and listed in the table of contents.

Physiology of the Parasitic Nematodes

Nematodes Parasitic in Animals

By Dr. Geoffrey Lapage. (Methuen's Monographs on Biological Subjects.) Pp. x + 172. (London: Methuen and Co., Ltd., 1937.) 4s. 6d. net.

THE scope of this excellent little book is not, as its title might suggest, systematic or faunistic. It is addressed primarily to the experimental biologist, and the author's chief concern is with the physiology of the parasitic Nematodes, upon which, as he points out, their relationships with their hosts depend, and a better knowledge of which might enable us to control their harmful activities in man and domestic animals.

There is an introductory chapter on the structure, life-histories and classification of the group. Here, in so condensed a work, it is perhaps inevitable that a few errors and questionable statements should creep in. It is doubtful whether "most nematodes are parasitic"; while it seems a pity to find the common misspelling of Filarioidea as "Filaroidea" constantly repeated.

The main part of the book, however, is a useful review of the mass of recent literature dealing with the mode of life and metabolism of the Nematodes, their effects on their hosts and the problems of

resistance to infestation. A bibliography of more than 400 references is given. His review leads the author to the conclusion that "in spite of every effort, no efficient control of any nematode parasitic in animals is known. . . . Work, therefore, which seeks to understand the physiology of nematodes is urgently needed. . . . No group of animals presents problems more interesting to the experimental biologist, nor a challenge more exacting to his skill. . . . If every biological laboratory in the world employed one experimental biologist on the study of parasitic nematodes, the reproach that neither biology nor medicine can cope with these parasites would soon be removed."

Our great ignorance of the physiology of these organisms, in spite of the work that has been done on them, is well brought out. The difficulties in the way of exact experiment are great. No one

has yet been able to keep alive a Nematode parasitic in a warm-blooded animal, outside its host, for more than a few days. It is also very difficult to exclude bacteria and other contaminating factors. As Dr. Lapege says, "the products of nematode-metabolism cannot be accurately determined until a completely sterile nematode can be studied".

After discussing the known facts concerning the resistance of animals to infestation with Nematodes, the author says that "the available evidence suggests that . . . the three kinds of resistance are different only in degree and not in kind", and is of the opinion that comparisons between such resistance and bacteriological immunity should be made with caution. Some possible methods of controlling infestation, mainly in grazing stock, are briefly discussed in the last chapter.

H. A. B.

Practical Hints in Horticulture

The Horticultural Note Book :

a Manual of Practical Rules, Data and Tables, for the use of Students, Gardeners, Nurserymen and others interested in Flower, Fruit and Vegetable Culture or in the Laying-out and Management of Gardens. Compiled by J. C. Newsham. Fifth impression. Pp. xx + 418. (London : The Technical Press, Ltd., 1937.) 7s. 6d. net.

THE new edition of this book follows on the lines laid down by its author in the original work. For conciseness and lucidity in pocket-book form, it would be hard to improve upon. Its data and practical details can be fully relied upon and the wealth of information crowded into its 418 pages covers the whole of the operations of any up-to-date garden. In this respect the author has a genius for imparting—in tabloid form—his wide knowledge to others.

A very large number of subjects bearing upon horticulture are ably dealt with. There are chapters on such widely different items as weights and measures, sizes of pots, land measures in detail, valuable information and full descriptions on the formation of kitchen and fruit gardens, lists of plants for each, costs of digging, trenching and drainage. The making of lawns and their upkeep, lists of grasses to use in various soils, buildings, sheds, fruit rooms, greenhouses and heating apparatus, are all dealt with separately in a thorough and practical manner.

Soils and geological formations are given a full chapter, and the chemical contents of various soils and manures are clearly defined.

Propagation by seeds, layers, grafts and cuttings is described in detail. There is a long chapter on fruit culture, which includes a useful list of varieties of all the best fruits grown in the British Isles. The best stocks to use for grafting, planting of various fruits, choice of sites suitable for each kind, picking, storing and even details as to packing and marketing are all fully discussed. No important item or detail has been left out and the whole work is brimful of most valuable information, all collected together under separate headings, and very easy to look up by the aid of a full and complete index.

In the 92 pages devoted to flowers and their culture, full lists of plants for the herbaceous border, greenhouse, stove and house decoration are given, and a feature of this is that all the principal florists' flowers are dealt with separately, with valuable notes on the time of flowering, height and colour of the flowers. A select list of ferns for stove, greenhouse and hardy conditions ; cultural notes on orchids ; lists of trees and shrubs for various soils and conditions ; notes on economic plants ; weeds of various kinds, and notes on the best method of eradication are included ; also, the rotation of crops, and even such out-of-the-way subjects as "The Natural Food of Wild Birds" ; "Points to be Observed in Judging" ; "The Economic Value of Timbers", and a whole chapter on "Insecticides and Fungicides".

For its size and completeness, there is nothing like this book as a valuable aid to both the amateur and professional gardener, and it is one that should be on every garden-lover's bookshelf.

The Nation's Intelligence

By J. L. Gray. (Changing World Library.) Pp. iv+154. (London: Watts and Co., 1936.) 2s. 6d. net.

The Menace of British Depopulation

By Dr. G. F. McCleary. Pp. 148. (London: George Allen and Unwin, Ltd., 1937.) 4s. 6d. net.

THESE two books, both conceived on scientific lines, and both written in the scientific spirit, are concerned with two momentous issues. One of them asks the question: Are we heading for national stupidity? The other asks the still more stirring question: Are we heading for national suicide?

In dealing with the first of these questions, Mr. Gray confronts the school of writers who hold that the offspring of the prosperous classes are on the average abler than the children of the poor in virtue of their superior mental inheritance, and who do not shrink from the inference that our high expenditure on social services, including education, simply encourages the perpetuation of inferior types, and ought, therefore, to be restricted. Arguing, as we have said, on strictly scientific lines, and without any social and political prejudices, Mr. Gray gives reasons for believing that there is no cause for alarm, that there is no ground for supposing that the average intelligence of the community is decreasing, and that, so far from being a blunder, the raising of the physical and intellectual level of the masses is of vital importance.

As to the menace of depopulation, Dr. McCleary sounds the definite note of warning. The population of Great Britain is still increasing, but, at a rate so greatly reduced as to point to the beginning of decrease in the near future. If, says he, our present fertility and mortality rates remain at their present level, we shall enter upon a period of decline which must end in extinction. Most people, by the way, do not realize the position, because they are misled by an unscientific and superficial view of the relevant statistics. As the same process is going on in most of the Overseas Dominions of the British Empire, and as the mother country will soon be able to do nothing to help them, the outlook for the Empire is a black one. The author is in no doubt that the main cause of the decline is voluntary birth-control. He sees little hope of stimulating the growth of population by such artificial expedients as family allowances and marriage loans. Yet he does not close on a note of despair. The effective remedy, he holds, lies in making life better worth living for all classes of the community.

Vakuumspektroskopie

Von Dr. Hans Bomke. Pp. x+248. (Leipzig: Johann Ambrosius Barth, 1937.) 17.70 gold marks.

SINCE the publication of Lyman's monograph "Spectroscopy of the Extreme Ultra Violet", there has been a steady development of technique and accumulation of results in the field of vacuum spectroscopy. Improved glass gratings and the use of grazing incidence have enabled the limit of the spectrum to be pushed to shorter wave-lengths, until now it is well within the long-wave limit of soft

X-rays. Many spectra have already been studied. It has thus become desirable that a new survey should be made of the investigations which have been carried out in this field. In his valuable little book "Vakuumspektroskopie" Dr. Hans Bomke has set himself this task.

Dr. Bomke opens with a brief historical review, then proceeds to describe in considerable detail the design of various types of vacuum spectrographs, their method of use and the construction of light sources suitable for them. About two thirds of the book are devoted to these topics. The remaining third is concerned chiefly with work which has been done on the spectra of atoms, although eight pages at the end briefly summarize results obtained with molecules and solid bodies. The appendix contains useful constants and a very full bibliography.

This book should prove of great assistance to those desirous of becoming acquainted with recent researches in the extreme ultra-violet.

A Text-Book of Inorganic Chemistry

Edited by Dr. J. Newton Friend. Vol. 11: Organometallic Compounds. Part 4: Derivatives of Selenium, Tellurium, Chromium and Platinum. By Archibald Edwin Goddard. Pp. xxviii+292. (London: Charles Griffin and Co., Ltd., 1937.) 20s. net.

THE subject-matter of the present volume is concerned with the aliphatic and aromatic derivatives of selenium and tellurium and the organic compounds of chromium and platinum. It is almost entirely of interest from the point of view of organic chemistry, and it may be suggested that vol. 11, dealing with organo-metallic compounds, four parts of which making up a total of 1,632 pages have already been published, is out of proportion with the rest of the work. In the present volume, very minute details of preparation are given and the text will be of interest mainly to the specialist. The literature appears to have been very well covered and there are good indexes. For those who wish to inform themselves of the subject of which it treats the book will be a very useful guide. The preparations are nearly always given in sufficient detail to make reference to the original publications unnecessary.

Practical Stereoscopic Photography

By J. Moir Daltzell. Pp. xv+224. (London: The Technical Press, Ltd., 1936.) 10s. 6d. net.

DR. MOIR DALTZELL's book deals with the minutiae of a single branch of photography. The subject is for the most part clearly treated, but the complete absence of illustrations renders some parts difficult to follow. In the early chapters the author discusses the characteristics of binocular vision, describing the psychological effects of various muscular actions and their relation to our interpretation of what we see. There follows a very complete treatment of apparatus and technique. Much of the part dealing with technique is applicable to general photography, and will be found very valuable to the 'one lens' workers as well as to stereo workers.

The Voyages of the *Discovery**

ABOUT forty years ago, the first *Discovery* lay a-building in Stephen's yard at Dundee, for Captain Scott's Antarctic Expedition. She was built like a Dundee whaler, but of the finest African oak, and finished as a labour of love; her timbers, spars and full barque-rigging were all as

Office built a new ship under her old name, less beautiful, but equipped as no other ship had ever been for the naturalist and the hydrographer. A much smaller vessel was added later on, bearing the name of that great scientific navigator and whale-fisher William Scoresby. She was built as

Fig. 1.

EARLY LIFE OF THE BLUE WHALE. FROM "REPORT ON THE PROGRESS OF THE DISCOVERY COMMITTEE'S INVESTIGATIONS".

strong as Stephen and his men could make them; but the old lines were not left unaltered, and when she put to sea she rolled terribly. The Hudson's Bay Co. got her later on, and the Colonial Office took her over when she was five and twenty years old and sent her on her first and last cruise to the Falklands and the South Georgian whaling-grounds. She found other Antarctic work to do under the Australian and New Zealand Governments, when our Colonial

a "whale-catcher", to study and mark the whale at close quarters; the Norwegian whaling-skippers at Walfisch Bay (when I happened once to pass thereby) thought they could have built her a great deal better; but still she has marked her whales, and done good work in other ways.

The old and new *Discovery* and their little sister-ship have been at work on and off pretty steadily for twelve years in the fierce cold and almost constant gales of Antarctic seas. Their one main object was to study, for the sake of the whale-fishery, the natural history of the several whales,

* Report on the Progress of the Discovery Committee's Investigations. Pp. 53+11 plates. (London: Colonial Office, 1937.) 3s. 6d. net.

their movements and migrations, the things on which they feed, the waters in which they live and move; physical oceanography, chemistry and all the biological sciences have their part in the story of the whale. The Basque harpooners in the Bay of Biscay killed out the Atlantic whales, one by one, until no more were seen for near a hundred years; the New Bedford men chased the Sperm whale all round the world, with ever-lessening catches; the Dundee ships in Davis Straits pursued the dwindling Greenland whale to the very verge of extinction. But the modern whaler, with his Svend-Foyn gun, his explosive bullets, and his 'floating factories', kills a hundred whales to the

most abundant whale in the Antarctic; the rarer Humpback was the first to show grave signs of depletion. Some 10,000 Blue whales are killed every year down in the Antarctic, besides a good many more (younger on the whole) on the South African coast; and, if the numbers killed do not yet become noticeably less, the mean size falls away, little by little and year by year. The whales do not live so long, their 'expectation of life' grows significantly less; worse still, the mean size over the whole catch is falling below that of first maturity—a larger and larger proportion of the remaining stock no longer breed at all! The Blue whale is about 21 ft. long at birth, nearly 60 ft. long (so it is said) at a year

old, and the females are sexually mature a little over two years old, when they are about 79–80 ft. long. This very rapid growth and very early maturity (on which the hopes and prospects of the fishery largely depend) are vouched for by the *Discovery* naturalists, and are in harmony with Norwegian estimates; they are novel, and unexpected, and extremely interesting determinations. Papers by Dr. Stanley Kemp, Dr. N. A. Mackintosh, Mr. J. F. G. Wheeler and Mr. A. Laurie on the Blue and Fin whale, their rate of growth, their age at maturity, their migrations, their estimated numbers, their curious physiology of respiration and all else about them, are here as large instalments of the work which the *Discovery* set out to do.

The *Discovery's* hydrographic work has proved peculiarly interesting, and Mr. G. E. R. Deacon deserves especial congratulation. Oceanography had its roots in the *Challenger* Expedition, its seeds were sown by Humboldt and Maury, but the tree only began to grow apace some thirty or forty years ago; it was then that Nansen told us something of the peculiar oceanographic interest of the polar seas. The *Challenger* had given us, as a first approximation, the simple story of a bottom-current, cold and heavy, flowing towards the equator, while a surface-current, salt and warm, streamed over it to the pole. That the great oceans show a more complex stratification than this was indicated even by the *Challenger* observations, as Merz saw long afterwards; but the Edinburgh physicists were cautious men, and had been afraid to trust to what seemed the too complicated evidence of their own thermometers.

Fig. 2.

OCEANIC CIRCULATION IN THE SOUTHERN HEMISPHERE. FROM "REPORT ON THE PROGRESS OF THE DISCOVERY COMMITTEE'S INVESTIGATIONS"

old harpooners' one; and it was plain to see that, plentiful as whales were on their southern feeding-grounds, they could not outlast the insatiable pursuit for ever. The aim of the *Discovery* was "to furnish a basis for the rational regulation of whaling"; in other words, to tell the commercial world how far greed might safely go. The whale is a very different thing, say, to a codfish, which lays, year by year at random, its million eggs; the whale nurses its single child for months with all solicitude, but men of business slaughter it as the Red Men killed the buffalo, and no humanitarian considerations enter the case.

The Blue whale, or Sibbald's whale as it was until lately called (after the old Edinburgh physician of three hundred years ago), is the largest and most valuable, the Fin whale (or common rorqual) the

Now the *Discovery*, following on the *Meteor's* work, gives us a new story just a little less simple than the old, telling of four water-layers in the oceanic circulation instead of two. Starting out from the Weddell Sea, toppling to begin with over the edge of the plateau, down to the bottom and away northward, goes a current of cold heavy water. Lying over this and creeping slowly southward, a mass of warm salt water lies; it rises up over the Antarctic current as this plunges down to the depths on its northward way, but it does not come to the surface, for there is other Antarctic water there with a density so far reduced by melting ice as to float, cold as it is, over the warm deep current. Then over all comes the fourth layer, of tropical or subtropical water, very salt but very warm, flowing southward over all the Antarctic waters.

The whole case, simple as it is, is not quite so simple as that! For our two surface-waters, the hot and the cold, the salt and the fresh, one going south and one coming north, meet somewhere, and when two water-masses meet things happen. You may see almost anywhere near the shore, especially in an estuary when the tide is coming in, a line of frothy turbulent water, marked out by a flotsam of sticks and straws; this is the *Schäumrand*, as Otto Petterson called it. Such a *Schäumrand* on a prodigious scale, visible from miles away, marks somewhere about 50° S. the so-called "Antarctic Convergence", the meeting of the warm and cold surface-waters. Here the south-going current is turned back or carried down, and mixes with the Antarctic surface-water which meets it, to form, some way below, the cold northward intermediate current. Thus in the farthest south we have *three* layers of water—cold, warm and cold again; but farther north there are *four* layers, tropical or subtropical ocean-water drifting southward over the other three.

From this easy beginning the story goes on and gathers interest. It is one of Deacon's remarkable discoveries that the Weddell Sea, and that alone, is the source of all the heavy bottom-water, heavy with cold and undiluted by melting ice; from the Weddell Sea the drift creeps along at the bottom of the great oceans, and is traceable even as far as the Bay of Biscay. But there are parts of the Antarctic Ocean so barred by shoals or submarine walls as to be shut off from the main current-system. Ross's Sea has a northern wall so high that the warm deep current does not enter it at all. So Ross's Sea becomes filled up with Antarctic water, extremely cold, and also extremely salt because much water has been removed to form pack-ice; and the fauna of Ross's Sea has (I believe) its consequent peculiarities.

Surface-currents coming northward from the far south hug the west coasts of the great continents,

and the most important and best-known of these, which the *William Scoresby* has specially investigated, is the Peru or Humboldt Current. It flows for more than 2000 miles along by Chile and Peru, now slow, now swift, now narrow and widening out again, even to a breadth of some 200 miles. It seems to arise about 40° S., in one of those convergences or divergences of which we have spoken, where cool and moderately saline water of Antarctic origin wells up from below the warm water of the equatorial counter-current, as indeed it continues to do for all its length along the western edge of the continent. The cold water comes up teeming with nutrient salts; it breeds a plankton-fauna of the richest kind; and this supports a population of whales, and of fishes preyed on by innumerable sea-birds the guano of which is sent all over the world. This cold current dominates the situation, but now and then persistent northerly winds check it or thrust it aside. Then comes *el Niño*, a new warm current upsetting the old equilibrium; the fish die in millions, the water stinks, the birds starve, the guano industry cries aloud. On the west coast of South Africa, at Walvisch Bay and Swakopmund, the same phenomena occur.

After this fashion the *Discovery* reports lead us to many interesting things—interesting chemically and biologically—and arising out of the plain facts of oceanography. At the bottom of the Weddell Sea are found gypsum, calcium oxalate and calcium citrate, the last two especially being of obscure origin and unknown at the bottom of any other sea. A vast abundance of life, microscopic and macroscopic, strikes every naturalist in Arctic or Antarctic seas, and the coldest of Antarctic waters are the richest waters in the world. The biologist is apt to ascribe this abundance to superabundant oxygen, such as the cold waters can dissolve; but that alone would not go far. The nutrient salts, the phosphates and nitrates, are the true limiting factors in the growth of that micro-vegetation with which the whole biological cycle begins. The tropical oceans are often very barren of these salts; in our own latitudes there is never too much, and the burst of growth in spring uses up the supply leaving little or nothing to spare; but the *Discovery* people have shown us that phosphates and nitrates are more abundant in the Antarctic Ocean than in any other seas, and that down there plant-growth is never checked for want of them. Plant-growth in the ocean is limited to a certain depth by its need of sunlight, so the water a little lower down tends to be rich in unused phosphates. In the neighbourhood of any great divergence these waters rise to the surface, and foster an unusual micro-vegetation there. At the edge of the continental shelf we meet with such

rising waters, and have again a richer growth of plants and of creatures great and small to feed on them and one another.

A hundred years ago, Johannes Müller was using the first tow-net, about the time when Edward Forbes was borrowing for the first time a fisherman's oyster-dredge; but only now do we begin to understand properly the importance of the floating life of the sea. Its distribution, its seasonal abundance, its variation with temperature, its presence in this water and absence in that, the vast variety of organisms of which it is variously and with varying importance composed, all these things are a great part of the science of the sea and of our understanding of all the fisheries. Prof. A. O. Hardy of Hull (a most ingenious student of the plankton) and Mr. E. R. Gunther have written an interesting report on the ways and means by which plankton is dispersed and distributed, and how the gathering-places of the whales may be expressed in terms of

plankton, and again of the phosphate supply. Dr. N. A. Mackintosh has demonstrated a seasonal circulation in the Antarctic plankton on a scale unrivalled elsewhere; the big Euphausias, staple food of the Blue whale, first made known by the *Challenger* and met with again by Dundee whalers who went far south unsuccessfully some forty years ago, are fully described by Dr. F. C. Fraser and Mr. Dilwyn John. But without saying more of the ship's company and their doings, let me just say that the *Discovery II*, with a great task to do and ample means to help to do it, has added largely and handsomely to natural knowledge, and given the ship's name an honourable place among voyages of exploration and discovery. There is one omission in the report before us. I have read it all through without encountering the name (save in a list of papers) of the leader and director of the Expedition, the distinguished author of the report.

D. W. T.

Tests in Common Use for the Diagnosis of Colour Defect*

By Dr. Mary Collins

TESTS for colour vision fall into two categories.

In one type of test, transmitted light is used, in the other reflected light. While the former type of test is regarded as the more fundamental, the latter can be of great service for quick diagnosis of colour anomaly. Colour tests may be administered purely for theoretical purposes, or they may be applied for practical purposes, as selection tests for different vocations. This second function assumes its most important role in vocations in which lack of accurate discrimination between different coloured signals may involve human lives. This function is also of significance in other vocations in which the lack of colour discrimination, though not involving danger to the community, is highly disadvantageous to its possessor.

There seems to be no need at the present day to emphasize the importance of the recognition and detection of colour defect. It is, however, very illuminating to study some of the more recent investigations in the field, particularly those concerned with the incidence of red-green defect. The percentages given seem to be much higher than in the reports of the earlier investigations. It does not necessarily follow that the incidence of the defect is increasing; the indications are rather that detection is more accurate owing to the

improvement of the test material. Out of 360 candidates applying for acceptance as apprentice printers, the percentage of red-green colour-blinds was 7.5, this figure being exclusive of the colour-weak and the anomalous.

It seems more or less agreed that red-green colour-blindness is a reduction system of normal colour vision, one cogent argument in support of this contention being that normal colour matches are valid for any type of dichromate. The colour-blinds lack something which the normal eye has, but have nothing which the normal eye does not possess. The individual with normal colour vision sees a spectrum composed of six or seven colours. The red-green colour-blind has a spectrum composed of only two colours, these two colours being yellow and blue. The acceptance of this fact was delayed for a long time, and it is doubtful if it is yet generally accepted. Herschel, in 1845, was the first to put forward the dichromatic explanation of colour-blindness. He pointed out in his article on "Light" in the "Encyclopædia Metropolitana" that certain individuals could only distinguish two colours, and that these two colours were yellow and blue. Clerk Maxwell, among others, opposed this, for he accepted the theory put forward at that time by Young and Helmholtz that colour-blinds were either red-blind, green-blind or violet-blind, and that the red-blind were blind to red,

* From the presidential address to Section J (Psychology) of the British Association, delivered at Nottingham on September 3.

but could see the remaining two colours, green and violet: the green-blind were blind to green, but could see red and violet.

In an account by Pole of his own case, we find he vigorously protests against these prevailing beliefs, and gives a careful analysis of his own colour vision as evidence. He had been pronounced red-blind by Maxwell and green-blind by Holmgren. Pole repudiated both suggestions, and claimed that the true solution was that he was blind to both colours. This conclusion was confirmed by a large number of facts. One was the evidence of the colour-blinds themselves who, whether they were classified as red-blind or green-blind, asserted that their colour sense was composed of blue and yellow. Another was a case of congenital unilateral dichromatism investigated by von Hippel in 1880. The individual tested had normal colour vision in his left eye but was colour-blind in his right eye. With the right eye he confused red and green with yellow, as tested by various standard tests. The colours which the subject could distinguish with his right eye were blue and yellow, these being confirmed when he looked at them with his normal eye. Von Hippel diagnosed the case as one of red-green blindness with spectrum of normal length. Holmgren examined the case with his wool test and proclaimed it to be one of red-blindness with shortened spectrum in accordance with the Helmholtz theory. Von Hippel retested his subject and reaffirmed his finding. This was the first case of monocular colour vision reported, and it undoubtedly strengthened the case for the acceptance of Herschel's and Pole's views. Holmgren, it is interesting to note, ultimately agreed that blue and yellow were the only colours seen. That this point is still controversial may be gathered from the statement made by Pitt in a recent investigation, that the fundamental responses of the protanope are blue and a saturated green, while those of the deuteranope are blue and a mixture of red and green.

Only a few cases of unilateral colour-blindness have been recorded, and these, according to Parsons, are of "doubtful value". In these cases, however, the suggestion is always that the colours seen are blue and yellow. Miles and Beaumont, who tested the two eyes separately in an investigation into colour-blindness, found considerable difference between the two eyes in many cases, and suggest that although there is no conclusive evidence as to the frequency of unilateral colour-blindness, "possibly it amounts to three or four per cent of the colour-blind". They discovered one such case in a group of 23, and Miles and Craig found another in a group of 390 mercantile salesmen. This latter individual was a dry goods

salesman and aware of his condition, and if required to match fabrics he closed the defective eye and made the proper discrimination with his normal eye. If these cases of unilateral colour-blindness are as numerous as suggested, a field seems opened up for further investigation which may lead to definite conclusions as regards the fundamental sensations of the red-green colour-blind.

The results of investigations carried out over a number of years at Edinburgh into the colour-sensations of the red-green colour-blind seem to indicate that their colour sensations are indeed blue and yellow. The extent to which these two colours replace all the other colours in the spectrum is, however, not constant for every colour-blind. With some, yellow and blue may replace all the other colours, that is, red, orange, yellow and green may be seen as different shades of yellow, blue and violet as different shades of blue. Sometimes, instead of the green being replaced by yellow, it may appear as grey, or the blue-green may appear as grey, the extent of the neutral band varying with the gravity of the defect. A second neutral band is also found extra-spectrally in the complementary colour, in the purples. In one extreme case which came under observation, only two narrow bands of yellow and blue existed, the other colours being seen as shades of grey. Red appeared as black, orange as dark grey, yellow could be discriminated, green and blue-green were seen as grey, blue could be distinguished, but violet appeared as dark grey. In one test, out of 76 colours observed, 64 of them appeared as grey.

All cases, however, are not so extreme as the one just described, and the general finding which seems to be gradually gaining ground is that there exist different degrees of colour-blindness extending from extreme cases in which blue and yellow are the only two colours visible, to milder cases in which the blindness to red and green is not total. In these milder cases the individual can see red and green if they are bright enough or vivid enough. It is these milder forms which constitute the great practical problem, for in these cases the ability to distinguish between red and green is likely to fail when the individuals are fatigued, or when the illumination is poor, as in mist or fog. The extreme cases can be easily detected, but the milder cases, which have been described as 'dangerous colour-blinds', require very careful examination if they are to be detected.

That different degrees of colour-blindness exist has been emphasized by more than one writer. Hayes "wonders if we shall presently have to give up all classifications by types, arrange colour defectives in distribution tables and give a colour graph or profile for each subject, showing his

efficiency or deficiency for each colour in terms of a per cent of the normal or average attainment". Troland states that the original restriction of colour-blinds to protanopes, deuteranopes and tritanopes is no longer adequate, and allowances must now be made for more types of variation. Edridge-Green recognizes seven different types of colour vision, and Schjelderup states that there are at least eighteen significant species of colour-blindness. Collins reaches the conclusion that it is quite unprofitable to try to classify the colour systems of the colour-blind because there exist so many individual variations.

One group in which the colour defect is not extreme has been definitely recognized. Seebeck, in 1837, found certain cases which he was reluctant to classify as colour-blinds, who yet showed signs of colour abnormality. It was not until 1881, however, that these cases were understood. In that year, Rayleigh found that a number of individuals with otherwise normal colour vision were unequally sensitive to red and green. In equating red (lithium line 670.8μ) and green (thallium line 535μ) to match a yellow (sodium line 589μ), since known as the Rayleigh equation, some were found to require far more red than the normal, others required an excess of green. Von Kries, in describing an extensive series of experiments, applied the name 'anomalous trichromates' to these cases, and this designation has gained universal currency. Guttman advocated the terms red-weak and green-weak, and distinguished seven characteristics which they manifest, the chief of which are high thresholds, heightened colour contrast and a quick fatigue to colour stimuli.

It is customary to divide these anomalous trichromates into two groups corresponding to the two groups of dichromates, deuteranomalous trichromates or partial deuteranopes in which the sensitivity to green is below normal, and prot-anomalous trichromates or partial protanopes in which the sensitivity to red is below normal. The

green anomalous seem to be more numerous than the red anomalous, the ratio being quoted as 5 to 1.

These cases, it may be, form the connecting link between normal colour vision on one hand and colour defect on the other, and if a sufficient number of cases could be tested ranging from normality to complete red-green deficiency, a continuous series might be obtained.

It is a moot point as to whether these anomalous trichromates form 'dangerous colour-blinds'. The general finding seems to be in favour of the affirmative. Some writers, for example, Troland, actually include them in classifications of types of colour-blindness. Oblath points out that they can only recognize colours when they are saturated and of intense luminosity; "It is evident that these peculiarities render these subjects less fitted for certain services". In a report on "Colour Vision Requirements in the Royal Navy" (Med. Res. Council Report, Spec. Series No. 185; 1933), it is stated that "the mildly anomalous trichromate can be considered a safe look-out. On the other hand, the unfit anomalous trichromate is, in many ways, a greater source of danger than the dichromate". The incidence of this anomaly is estimated, in the same report, as 6 per cent, which is stated to be a very conservative estimate. Both reports emphasize very strongly the fact that the anomalous trichromate behaves as if colour-blind when conditions are unfavourable, such as when mist, fog or smoke are present, and this is all the more disastrous because the individual is rarely aware that he suffers from any colour defect. The heightened contrast and the quick fatigue characteristic of such anomaly may well make the judgment of colour and the discrimination of colour highly erroneous. The testing and discovering of these cases of anomalous trichromatic vision is not easy, and necessitates very careful procedure, and generally not the application of one test, but of a battery of tests.

(To be continued.)

Obituary Notices

Sir David Orme Masson, K.B.E., F.R.S.

PROF. SIR DAVID ORME MASSON, who died at Malbourne on August 10, was born at Hampstead, London, on January 13, 1858. He was of mixed English and Scots descent. His father, Prof. David Masson, editor of *Milton*, *Goldsmith* and *De Quincey*, and *Historiographer-Royal* for Scotland, came of Aberdeenshire stock—there is a saying in the Don valley that "Eassons, Massons an' Kessons a' cam' frae Tarlandside". His mother, Rosaline Orme, had a forbear George Rutt, the father of

Joseph Priestley's biographer, John Towill Rutt; and it may be mentioned, as throwing some light on the family, that the home of the Ormes, in Avenue Road, Hampstead, was a favourite rallying ground of the Pre-Raphaelites. In 1865 David Masson migrated from the chair of English literature at University College, London, to the Regius chair of English in the University of Edinburgh, and so it came about that his son, David Orme Masson, was educated at Edinburgh Academy and afterwards graduated M.A. and B.Sc. at Edinburgh.

In his younger days Masson was a strong walker and swimmer, and he played golf, tennis and billiards. After a short period of research with Prof. Crum Brown, he left Edinburgh for Bristol in 1880, to become Prof. W. Ramsay's first assistant (in later days, his son, Irvine Masson, was to become Sir William Ramsay's last assistant, at University College, London). Before Masson returned to Crum Brown, he and Ramsay had laid the foundations of a lifelong friendship. Meanwhile he had acquired some further research experience at the University of Göttingen. During his second period at the University of Edinburgh, Masson, with R. Fitzroy Bell, founded the first Students' Representative Council in any university, of which Masson became the first Senior President. The ensuing revolutionary improvement in the students' behaviour at graduations, etc., led Principal Sir Alexander Grant to exclaim, at the end of the tercentenary celebrations: "Gentlemen, you have saved the Republic!" Masson was also a prime mover in the foundation of the Students' Union in the University of Edinburgh—again, the first in Great Britain.

In 1886 Masson was elected to the chair of chemistry in the University of Melbourne, a key appointment which he held with high distinction until he retired in 1923, to become professor emeritus. Orme Masson, and his contemporaries Baldwin Spencer and T. R. Lyle, must be numbered among the prime creators and moulders of Australian science; to them Australia in general and the University of Melbourne in particular owe a debt beyond computation. A brilliant and inspiring teacher, Masson built up Australia's most distinctive school of chemical research at Melbourne, and exerted a steady influence upon the development of Australian science through his pupils and research students; but this was only one side of his work. His remarkable clarity of vision, combined with his organizing and administrative ability, his interest in the wider aspects of science, and his flair for public work, naturally brought him out as a leader in the foundation of national scientific institutions in Australia. Among these were the Commonwealth Advisory Council of Science and Industry, of which he was deputy chairman from 1916 until 1920, and which merged later into the Commonwealth Council for Scientific and Industrial Research; the Australian National Research Council, of which he was president in 1922–26; and the Australian Chemical Institute, of which he was the original president in 1924. Masson was also president of the Australasian Association for the Advancement of Science in 1911–13, and was largely instrumental in bringing about the visit of the British Association to Australia in 1914. In addition to all this, he was active in the interests of Antarctic exploration from Australia.

Masson's researches were concerned chiefly with physical chemistry, more particularly with the theory of solutions, ionization, and chemical dynamics. With Ramsay, at Bristol, he worked upon atomic volumes at the boiling point¹. This investigation was followed, at Edinburgh, by some work with M. Hay on the composition of nitroglycerine², and

by a series of researches on sulphine salts, carried out partly in collaboration with L. Dobbin³. The latter theme was afterwards extended at Melbourne with J. B. Kirkland⁴. A paper on molecular volumes⁵ was followed by another early research at Melbourne, in which, with N. T. M. Wilmore, Masson came near discovering the celebrated organic synthetical reagents later associated with the name of Grignard⁶.

In 1891 Masson pointed out the analogies between solution and vaporization which are embodied in his term 'critical solution temperature'; at the same time he brought to notice certain other principles regulating the miscibilities of liquids⁷. He was a keen exponent of the ionic theory in its early days, and between 1897 and 1899 he developed the direct 'jelly-tube' method of measuring ionic velocities⁸. Later notable work emanating from the Melbourne laboratories under his inspiration included various observations on the decomposition of persulphates and of sulphine hydroxides in aqueous solution (Leila Green, Brenda Sutherland⁹), and studies on the viscosity and conductivity of some aqueous solutions (W. Heber Green¹⁰). Another interesting research (1909), dealing with the mechanism of urea-formation from cyanates, was carried out in collaboration with his son, Irvine Masson¹¹. During this period also, B. D. Steele and Kerr Grant¹² developed their quartz micro-balance in Masson's department; this was afterwards used by Ramsay and Whytlaw-Gray to measure the density of radium emanation.

It is not generally known that early in 1895 Masson evolved a modification of Mendelëeff's periodic system, which, apart from the treatment of the rare-earth metals, is practically identical with the later classification of Bohr. Masson's arrangement was printed immediately after Ramsay's discovery of helium¹³, and it contained spaces which were later filled by neon, krypton, xenon, and niton. "Helium and Argon," it is stated in an inset to the table¹⁴, "are placed in the new Group VIII, characterized by valence = 0 and atomicity = 1." It was probably a discussion between Masson and Ramsay in May, 1895, during a visit of Masson to Great Britain, which first gave Ramsay real confidence in the idea of this missing group of rare elements. Masson's arrangement was adopted by Ramsay and incorporated by him in a celebrated wall-diagram which he used in his lectures at University College, London (part of this diagram was reproduced in the well-known caricature of Ramsay by 'Spy').

Another example of Masson's prescience is provided by a paper published so early as 1921, in which he developed what was essentially a proton-electron statement of the composition of atoms and of the consequent form of the periodic classification¹⁵. This striking treatment of a fundamental problem failed to attract the attention it deserved. A similar remark applies to Masson's final contribution to physical chemistry. This work, which was summarized in a paper brought before the Australasian Association for the Advancement of Science in 1935, and afterwards printed, offered a new treatment of the facts of the electrolytic conductivity of strong

and feeble electrolytes, in strong and weak solutions, from which Masson deduced a simple general law based upon the viscosity aspect.

Masson's direct contacts with industrial chemistry were limited, but a constant stream of his students went forth into industrial careers in Australia and elsewhere. Through the close touch which he maintained with his former students and their firms, he exerted a wide influence in this field, directed particularly towards the scientific management of industrial concerns. Among his old students who entered academic chemistry may be mentioned his own successors at Melbourne, Prof. (now Sir) A. C. D. Rivett and Prof. E. J. Hartung, and elsewhere Prof. L. S. Bagster, Dr. A. O. Cumming, Prof. J. I. O. Masson, the late Prof. B. D. Steele, and Prof. N. T. M. Wilmore.

Masson's work received early recognition in his election to the Royal Society in 1903. He became C.B.E. in 1918, K.B.E. in 1923, and LL.D.(Edin.) in 1924. He married Mary, daughter of the late Prof. Sir John Struthers, M.D., of Aberdeen and Edinburgh, who survives him; of his two daughters one survives; and his only son, Irvine Masson, is professor of chemistry in the University of Durham.

David Orme Masson was a man of great charm and urbanity, with a rare gift of lucid exposition and a lively and polished wit. Modest, versatile, and cultured as befitted his ancestry, he possessed an unusually wide range of interests and human sympathies. He was the doyen of chemistry in Australia, a great teacher in the University of Melbourne, and a much-loved citizen of his adopted country.

Canon B. H. Streeter

CANON B. H. STREETER, provost of Queen's College, Oxford, who was killed with his wife in an aeroplane accident in Switzerland on September 10, was one of the great Biblical scholars of the world. He was a many-sided man, and his intellectual interest was wide. Psychology, modern physics, anthropology, psychical research, the relations between religion and science, were all subjects in which he had read widely and become interested. He had a large circle of friends from whom he could acquire at first hand the information on these subjects he needed. He was, in particular, profoundly alive to the difficulties raised by the relations of science to

religious truth, and some of these were discussed by him in his most popular book, "Reality: A New Correlation of Science and Religion" (1926), more briefly also in "Adventure" (1927), and in the Bampton Lectures for 1932, "The Buddha and The Christ".

By 'religion' Streeter meant religion and not, as so often in similar discussions, theology. In religion as implying a quest for God, an apprehension of things beyond the limits of ordinary experience, he was a firm believer. In "Reality" he discussed the connexion between this and science, as he conceived it, clearly and simply. He held strongly that religion, like science and art, reveals to us genuine aspects of reality. Science, he said, gives us a representation of ultimate reality diagrammatic rather than pictorial; religion the reverse—it gives us the picture, not the exact diagram. The two aspects are there; in a sense they are complementary; they are not, however, commensurable. He put it in another way. Science is concerned with the metrical aspects of existence, religion (as art) with non-metrical or qualitative aspects, with values that are mostly ethical. Science states definitely; religion suggests. One tries to explain what is observed by finding laws covering individual cases; the other isolates an individual event or circumstance and makes it symbolic of some aspect of reality. For Streeter the truth of religion lay mainly in the quality of the myths (in the Greek sense) it embraces. The values enshrined or symbolized there are inherent in reality to the extent that the religion is true.

In the eighth Bampton Lecture Streeter, discussing psychical research, gave some of his own experiences of suggestion, mass-hypnotism and telepathy. In particular he discussed the 'levitation' of D. D. Home in 1871 witnessed by the Master of Lindsay and two friends present. He suggested from his own successful repetition of this exploit that Home probably gave each of the three a 'waking suggestion' which effectively convinced them that what they attested actually occurred.

Streeter was born at Croydon in 1874 and educated at King's College School. He went to Oxford as scholar of Queen's College in 1893 and thereafter spent most of his life there. As undergraduate he obtained three first classes and many university prizes. He was fellow of Pembroke from 1899 until 1905 and of his old college, Queen's, from 1905 until his appointment as provost in 1933. He was a fellow of the British Academy and honorary doctor of several universities. He married in 1910 but had no children.

A. S. R.

WE regret to announce the following deaths:

Dr. J. R. Airey, formerly principal of the City of Leeds Training College, on September 16, aged sixty-nine years.

Prof. de Burgh Birch, C.B., emeritus professor of physiology in the University of Leeds, on September 18, aged eighty-five years.

Mr. F. A. Potts, University lecturer in zoology in the University of Cambridge, on September 15.

News and Views

Prof. G. Barger, F.R.S.

THE appointment, which is announced elsewhere (p. 558) of Prof. G. Barger, professor of chemistry in relation to medicine at the University of Edinburgh, to the Regius chair of chemistry in the University of Glasgow, will give general satisfaction. By his work during the past thirty years, Prof. Barger has exercised a considerable influence on the development of organic chemistry and biochemistry in Great Britain. In his well-known early collaboration with Dr. (now Sir Henry) Dale, in the laboratories of Messrs. Burroughs, Wellesome and Co., he was jointly responsible for one of the most fruitful applications of organic chemistry to biological problems which has ever been made; he is a distinguished worker in the field of alkaloid chemistry and by his own work and through his pupils he has made major contributions to what may be called in general terms organic biochemistry. Prof. Barger's appointment in 1919, after holding the professorship of chemistry at the Royal Holloway College, London, to the newly instituted chair of chemistry in relation to medicine at Edinburgh, was in itself a recognition of the outstanding characteristic of his work, namely, the attack of organic chemical problems related to biology not from a narrowly chemical point of view but with true appreciation of their biological implications. His Department at Edinburgh has continued to work on these lines, and has at the same time been responsible for great improvements in the teaching of chemistry to students of medicine. Prof. Barger's influence in chemistry to-day is further enhanced by the many contacts which he maintains with colleagues in other countries, aided as he is by linguistic attainments of distinction. It is encouraging to those who believe that organic chemistry has still vital contributions to make to biology that an important chair of chemistry such as that at Glasgow should be occupied by one who has shown the keenness of his biochemical interests by his own sustained efforts and through the work of his pupils.

Memorial to Samuel Smiles, LL.D.

IN the latter half of the last century a book called "Self Help" was widely read, and an indication of this is shown by its having been translated into twenty-two languages. It developed from a lecture given by Dr. Samuel Smiles in the old Cholera Hospital, Leeds, to a mutual improvement class of working men. Smiles was born in 1812 at Haddington and educated at the Burgh School and at the University of Edinburgh, where he qualified as a medical man. Not having sufficient patients, he wrote articles, and these were seen by the proprietor of the *Leeds Times* who in 1838 asked him to be editor. In 1842, having then "had enough of unquiet life of newspaper work", he set up as a surgeon in Holbeck,

South Leeds. He was partly attracted there by the activities of a school and in his autobiography he says: "On Sundays I taught young men and sometimes gave addresses in Zion School, New Wortley." Smiles married the daughter of a Leeds contractor and in 1845 became secretary of the Leeds and Thirsk Railway, which was afterwards absorbed into the Midland Railway system. This occupation brought him into contact with engineers, and he began to collect data which later appeared in his five volumes of the "Lives of the Engineers"; "Industrial Biography"; "The Lives of George and Robert Stephenson", etc. By his writings and lectures, etc., he helped to create in the West Riding a strong public opinion on such questions as the repeal of the Corn Laws; Parliamentary reform; national education and free public libraries. Zion School was one of the first to have such a library. A memorial tablet in bronze is to be fixed on the old school building, and a set of his books has been presented by Sir John Murray, whose firm published them. Sir Walter D. Smiles, M.P., is also presenting an enlarged framed portrait. The organizer of the memorial is Mr. E. Kilburn Scott, of 38 Claremont Square, London, N.1.

"Shiva's Temple", Arizona

WIDESPREAD interest has been aroused by the investigation of "Shiva's Temple", in the Grand Canyon, Arizona, U.S.A., which is being explored by the Paterson-American Museum Grand Canyon Expedition, with Dr. Harold Anthony, curator of mammalogy in the American Museum of Natural History, as its leader. Shiva's Temple, an isolated cliff of limestone, rises to a height of 1,200 feet above the floor of the Canyon, and is surmounted by a wooded plateau two hundred and seventy-five acres in extent, which is reputed never to have been visited by man since the cliff was separated from the mainland at some time about the close of the Ice Age. It was anticipated that forms of animal life, if any, surviving on the plateau after so lengthy a period of isolation might afford valuable evidence of adaptation and divergence. Dr. Anthony and Mr. Edwin McKee, chief naturalist of the Grand Canyon National Park, with six other members of the expedition, reached the plateau on September 16 after a three hours' climb. Shed antlers of deer were seen, as well as chipmunk, a rabbit and signs of coyote. The first specimens brought to the base camp were a pair of leaf-eared mice. Traps have been set for other animals by Dr. Anthony, who remained on the plateau when other members of the party returned to the base camp. Supplies were dropped from an aeroplane, including water, of which no trace has been found on the plateau. This makes it remarkable that the party should have been much troubled by mosquitoes.

It would appear that before it was isolated, the plateau was a favourable hunting ground for early man. A number of stone arrow-heads and knives have been found. Unless these are the relics of an early party of adventurous climbers, which seems unlikely, they should help in assigning a date to the period of isolation, more especially if the arrow points should conform to the highly specialized type of stone implement known as the Folsom point, which is widely distributed over the High Lands of the south-western United States from Wyoming to New Mexico, though not yet found in characteristic form in Arizona. As mentioned below, stone implements have been found recently in South America in association with the extinct horse and giant ground sloth, while Folsom points have been found embedded in the bones of an extinct bison, as well as in association with that form and with the mammoth, at Folsom and Clovis in New Mexico and elsewhere. It is now beyond question that in certain parts of North America early man was contemporary with an extinct fauna which in Europe would justify a Pleistocene dating in the later part of the Ice Age. In America, however, it is generally conceded, the characteristic Pleistocene fauna, or at least certain members of it, may have survived to a much later date than in the Old World, while conditions militated against a very early appearance of man in the New. If the implements of Shiva's Temple are of the earliest type, and belong, as appears probable, to the pre-isolation period, they indicate on a conservative estimate an upward limit for the period of isolation of approximately ten thousand years, or possibly a little but not much more.

Ancient Man in Chile

AN expedition to Chile of the American Museum of Natural History, New York, extending over a period of two and a half years, is reported to have discovered a succession of stone age industries claimed to be of greater antiquity than any previously known in South America. More than four thousand stone implements, it is stated by Science Service, Washington, D.C., have been collected by Mr. and Mrs. Junius Bird, on behalf of the Museum, from two cave sites, Fell's Cave and Palli Aike Cave on the banks of the Rio Chico in southern Chile, near the Straits of Magellan. In the former of the two caves was a stratified succession of five cultures, of which the earliest included tanged spear-points, unique in South America, associated with the bones of the extinct horse and giant ground sloth. This culture was covered by a rockfall, while at Palli Aike, twenty miles away, the oldest culture period closes with a deposit of volcanic ash. Some considerable time after the fall of rock, Fell's Cave was again occupied by man. With the artefacts of this period are associated at first bones of the horse and ground sloth, and later of foxes, of which one form is extinct, and birds. The implements are cruder than those of the early stage. In this and the preceding period the animal bones have been split for the extraction of marrow and show the effects of fire.

The succeeding culture introduces the bola, of which the carefully grooved weights have been found with the stone graters used to make the grooves. Arrow points and knives appear with the bola in the fourth culture, which is dated tentatively at 2000 B.C. on comparative evidence. The last occupants of the cave, who show no affinity with their predecessors, were the possessors of a culture in many ways comparable with that of the Ona of Tierra del Fuego, who, up to a few years ago, used stone arrow-points similar to those found in the cave. The cave seems to have been abandoned before the Spanish conquest, as no bones of the horse then introduced into America have been found in it.

University Development at Birmingham

It is reported that the University of Birmingham is selling the Mason College site, and the price is said to be £400,000. If the negotiations are satisfactorily completed, the long-desired transfer of the whole of the University to the Edgbaston site will soon be an accomplished fact, and the uneconomical and very inconvenient separation of the faculties will be a thing of the past. Already the building of the new medical school (between the great new hospital and the University at Edgbaston) is nearing completion, and it is hoped that the school will be ready for opening next year. Such an event would be a fitting crown to the work of the Vice-Chancellor (Sir Charles Grant Robertson) who has expressed his intention of retiring at the end of the coming session and who has taken a leading part in the establishment of both hospital and medical school. The money resulting from the sale of the Mason College site will also make possible the expansion, and improvement of the equipment, of some of the departments already at Edgbaston, the Physics Department in particular, which is at present partly housed in old Army huts, inconvenient and unsightly.

Health and the Community

IN the account of the discussion in Section I (Physiology) of the British Association on "Health and the Community", which appeared in NATURE of September 18, p. 493, it is stated on p. 494 that the safest rate of reproduction for both mother and offspring is the modal rate. The author of the article has asked us to point out that this statement holds for any size of family, but the example of modal rate actually given was for a family of seven. This does not bear the implication that seven is the ideal number per family. Actually the lowest mortality was found in families of three, produced *at the modal rate*. The author has also sent the following supplementary note. "One point in the discussion of immense importance for the future not only of the race but also threatening civilization itself, was not sufficiently stressed in the article, namely, the *differential* birth rate. It follows from the facts that the modal rate is, on the whole, observed only in the lowest paid members of the community, and that they start reproduction early (less than twenty years of age), that the number of the population

below the poverty line, that is, those being maintained by the tax-payers, will steadily increase. In 1930, round about 10 per cent of the families had more than 40 per cent of the pregnancies, 45 per cent of the still-births, 53 per cent of the infant plus child mortalities and 63 per cent of the miscarriages. In 1950, the 10 per cent will have become at least 30 per cent. Nothing short of massacre can alter that now. Births cannot be retrospective. If nothing is done and the process goes on, in 1970, the submerged tenth will be multiplied by seven. This means that, apart altogether from the increasing load of old people, some 30 per cent of the population will have to face the problem of supporting the rest of the community."

The Short-Mayo Composite Aircraft

EXPERIMENTAL flights of the two units of this combination are proceeding successfully at Rochester. *Mercury*, a four-engined monoplane seaplane, which is to be attached to the top of, and launched from, *Maia*, a four-engined monoplane flying boat of a modified Empire type, have both flown separately, and have now to carry out trials, taking off, flying and landing as a combined unit. These will be followed by tests involving releasing in the air and landing as separate units, their normal functions. This experiment is one of fundamental importance in the problem of high-speed long-range flight, as it represents one of several possible methods of getting an aircraft into the air with a load which would make taking-off unsafe or even impossible for a machine under its own power. Heavy loads are not only economical from the transport point of view, but also high wing loading is essential for economical power consumption in high-speed flight. Reduction in engine power used not only reduces costs, but also increases the machine's range on a given fuel tank capacity. When this problem is successfully overcome, it will also help in the case of land aircraft, allowing the use of smaller aerodromes for large heavily loaded commercial machines.

ANOTHER point of the composite type of aircraft is that it will allow the engines of the launched machine to be of the supercharged type necessary for high altitude flying, without their having to carry the complications necessary to allow them to function efficiently at ground level, for the purpose of taking off, as well. Other methods of attaining the same object at present being developed are (1) the use of various wing attachments such as slots or flaps, wing surface and contour changing devices, variable pitch propellers, to increase the speed range of the aircraft, and (2) catapulting the machine into the air, giving it the speed necessary for flight with its high loading, from a momentum applied to it from an external source of power, usually either explosive or hydraulic.

Progress of Marine Engineering

On September 14, Mr. S. J. Pigott, director-in-charge of the Clydebank Works of John Brown and

Co., Ltd., where the *Queen Mary* was built, delivered the presidential address to the Institute of Marine Engineers. In the main it was a review of the development in marine engineering during the last sixty years. The era 1877-87, he said, might be designated "The Advent of Steel in Engineering". In that decade it was possible to raise the pressure in cylindrical boilers to 160 lb. per sq. in., and at the same time forced draught was introduced. The next decade, 1887-97, saw the development of the quadruple-expansion engine, which in the period 1897-1907 attained its maximum size. The year 1897 was also marked by the use by Sir Charles Parsons of the marine steam turbine, and in 1904 the Cunard Steamship Company equipped the *Carmania* with a high-pressure turbine driving a centre-line shaft and exhausting to a low-pressure turbine on each wing-shaft. The Diesel engine first made its appearance on shipboard in 1903 in the small Russian tanker *Vandal*. Another landmark was the fitting of geared turbines in the *Vespasian* in 1909. In 1910 impulse turbines as opposed to the earlier reaction turbines were fitted in H.M.S. *Bristol*, and to-day, the most highly powered British naval vessel, H.M.S. *Hood*, is propelled by impulse turbines with gearing. If the era 1927-37 has seen no epoch-making development, it has produced progressive designs as is seen in the cross-channel motor-ship *Prince Baudouin*, the turbo-electric P. and O. liner *Viceroy of India*, and last but not least the *Queen Mary* and *Normandie*.

Miniature Ball Bearings

AN invention which, apart from its intrinsic merits as a mechanical development, promises to be of especial interest in a scientific sense, is the introduction by a Swiss manufacturer of a range of miniature ball bearings. Ordinary bearings of this class have been made in sizes varying from half an inch to five feet in diameter overall; but nothing small enough has been available to satisfy the requirements of small and sensitive instruments. The bearings now obtainable as a result of this invention are of several different types and vary in size from 1 to 22 millimetres in diameter overall. They are thus of suitable size for use in such devices as small motors, recorders, meters, clockwork, tachometers and scientific instruments of many kinds in which measured movements are produced by infinitesimal forces, and friction must be eliminated as far as possible. Comparative tests on these bearings and the jewelled bearings they are intended to replace show advantages under three different modes of operation. The time to damp down a rotary motion was in some cases so high as eight times that when plain pivots were used and twenty times that when tapered pivots were used, though there is a good deal of variation in the results. In an oscillatory test the corresponding figures were about 4 and 15, while in the deviation test the results claimed are also favourable. As these new bearings are obtainable at moderate prices, it is probable that, after adequate trials, they will play an important part in the

future construction of scientific instruments. They are being marketed by International Technical Developments, Ltd., Thames House, Millbank, London, S.W.1.

The Wettest Place in the British Isles

DR. J. GLASSPOOLE, in an article entitled "The Wettest Place in the British Isles", which appears in the *Meteorological Magazine* of July, seeks to end the false idea so commonly held that Seathwaite, in Borrowdale, is the wettest place in Great Britain. He points out that there are several small areas nearly twice as wet as Seathwaite, and suggests that the common error has lasted so long because meteorological literature has not provided definite figures to disprove it. This lack of precise information has been due to the lack of rain gauges near the summits of the highest mountains in the four wettest areas over which the average annual rainfall exceeds 150 inches—areas in Snowdonia, the English Lake District, on Ben Nevis, and at the head of the River Garry in the western highlands of Scotland. Dr. Glasspoole considers that in the light of records now available and a study of the relationship between average rainfall and the configuration of the land, estimates can be made of the maximum rainfall in each of the four areas. In Snowdonia we have Glaslyn, at 2,500 feet, with 198 inches, which is probably a little less than the figure for the summit, only about 500 yards away. In the Lake District it is thought that 185 inches is not exceeded in the wettest area, which includes Scafell and Scafell Pike, while Ben Nevis, in spite of its greater elevation, is more isolated and in consequence offers less obstruction to the moisture-bearing winds, and its summit has a rainfall estimated at only about 165 inches. At the head of the River Garry, however, the fall on Sgurr na Cioche is thought to be comparable with that of the summit of Snowdon over a small area, namely, about 200 inches, compared with the 129 inches of Seathwaite Farm, which last is not even the wettest habitation in Great Britain.

Fortified Hill-top Site in Sussex

A ~~fortified~~ hill-top site on Mount Caburn, one mile north of Glynde, near Lewes, has been partially excavated by Dr. A. E. Wilson of Brighton Grammar School with the assistance of Dr. E. Cecil Curwen. Since July, it is reported in *The Times* of September 14, portions of the outer and inner ramparts and a length of Iron Age road, with three gateways, have been uncovered. Of the gateways, one on the north side of the town, where the slope is comparatively easy, is of considerable size and is provided with re-entrant ramparts on either side for purposes of defence. A number of sling stones were found. The steep slope of the south side was defended by ramparts and a deep ditch. There are indications in the ceramic evidence that the site was first occupied about 500 B.C., and was fortified about two hundred years later. Stratification revealed by trenching suggests two periods of reconstruction, one about 50 B.C., when the main gate was moved a few feet forward, and a second about one hundred years

later, when a second gate, forming a sort of barbican, was added. Piles of ash near this gate may be, it is conjectured, either a relic of the process of hardening the ends of oak stakes to be driven into the ground, or evidence that the town was destroyed by fire. Flint kerbs mark the edges of the Iron Age roadway, of which the surface is reinforced by flints at a distance of four feet six inches apart, indicating that the gauge of the prehistoric cart was approximately the same as that of the modern cart. One of the ramparts shows what appears to be an early attempt to mix a concrete, powdered chalk apparently being mixed with water and rubble. A grant of £20 made by the Sussex Archaeological Society has made it possible to continue the work of excavation until the end of October.

Prehistoric Finds at Glasgow

EVIDENCE, it is claimed, indicating the site of a wooden circle, or temple, the largest of its kind yet known, has been found at Knappers, on the Dumtocher Boulevard, Glasgow. The site has been under investigation for some weeks by Mr. Ludovic McLellan Mann and Capt. Robert Bush Black, the proprietor of the land. The circle, it is reported in *The Times* of September 15, has a radius of 86 ft., the ground plan being revealed by the socket-holes which held the wooden posts and showing a symmetrical arrangement, "involving circles, ellipses and a large number of serpentine figures". A cemetery adjoins the circle containing fifty-three burials, both cremated and inhumed, with grave furniture and stone settings, many of which are said to be of an unusual nature. The associated funerary vessels fall into four classes and indicate both stone and bronze age datings. For the further exploration of the site financial assistance is required. Should this be adequate the site will be preserved and the monument reconstructed. Donations should be addressed to Mr. J. Eric Fergusson, 166 Buchanan Street, Glasgow.

Educational Films

FROM the British Film Institute we have received three lists, intended for the use of teachers, of about a thousand 16 mm. films: "Geography Teaching and Travel" (about 600), "Science" (400) and "History" (30). Against the title of each is shown its length, whether silent or sound, reference to report, if any, in the Institute's monthly film bulletin, and name and address of distributor. A large majority of the films are silent. Among the sound films are thirty "road-shows" obtainable through Sound-Services, Ltd., which provides a complete projection service in combination with the hire of films. The other sources of supply are very various: camera makers (Kodak, etc.), trade publicity organisations (Australian and Canadian), railway and other travel agencies (L.M.S., Scottish, German, Dutch), firms specializing in educational films such as British Instructional Films, Ltd., Educational Films Bureau, Educational and General Services, Ltd., Gaumont-British Equipment, Ltd., Visual Education, Ltd., and Dance-Kaufmann Technical Films; also the Empire Film Library,

G.P.O. Film Library and the National Film Library of the British Film Institute. Of the science films more than half are classified as zoology; others as physics and meteorology (72), botany (40), mathematics, astronomy, chemistry, geology, physiology and applied science. The prices, exclusive of postage, are: geography, 6d.; science, 4d.; history, nil. The Institute also issues lists of films dealing with agriculture and industry and catalogues of British medical films. The lists should prove useful to teachers, especially those who do not have access to the National Encyclopaedia of Educational Films. The Institute co-operated with the Educational Handwork Association in organizing a Film School, held in the University of London Institute of Education on July 26–August 6, at which there were lectures on the use of the film in school, film making for teachers, technique and manipulation, etc.

The Carnegie United Kingdom Trust

THE Carnegie United Kingdom Trust's annual reports are always worth reading, not only for the intrinsic interest of the Trust's achievements but also as revealing the latest developments of the administrative policies gradually evolved by the trustees. Co-operation with other trusts and relation to Government services are two aspects of the Trust administration that tend to call increasingly for careful study, owing to recent creations of other and comparable trusts and the ever-increasing liberality of the statutory services, notably since the inauguration of the Government's national health and youth programme. In this connexion, the report for 1936 notes that the Trust's playing fields policy, which has been completely successful, has now been discontinued, the future fulfilment of its objects having been sufficiently secured. Of the various land-settlement schemes which the Trust has been helping to finance, very encouraging accounts are given. "One of the most striking features of the new full-time holdings is the brightness of spirits of the whole community", although most of the men (about 110) had been unemployed for several years. Part-time subsistence holdings (about 1,000 in all) have been an immediate success in nearly every district where they have been established. Of the village halls the Trust has helped to finance, the report says their existence "has given new life to the community. Other recipients of the Trust's help during the year were: young farmers' clubs, the National Council of Social Service, new estates' community centres, amateur music societies, conductors' schools, adult education (inquiry into social and educational needs of the 18 + age-group), museums and libraries.

University or Polytechnic

IN the current issue of *Queen's Quarterly*, a Canadian review, "The Higher Learning" is discussed by Dr. R. C. Wallace, formerly president of the University of Alberta and now principal of Queen's University, Ontario. He refers to a recent assessment by R. M. Hutchins, president of the University of Chicago, of "The Higher Learning in America" (Yale

University Press) which confirms Abraham Flexner's estimate of the modern university. Admitting that there is a tendency for the university to become a mere congeries of professional schools deserving rather the name of polytechnic, Dr. Wallace rejects the suggested remedy—the severance of professional schools from the university and the restriction of the university's field to the fundamental sciences and mental discipline, such as metaphysics. He argues that the aim of liberalizing university education may be realized by invigorating and revitalizing the arts school, establishing a system of organic connexions and interchange of thought between it and other parts of the university so that its influence may permeate them all, and selecting for key positions in the professional schools persons of wide sympathies and philosophic outlook capable of using professional courses as instruments of mental culture as well as of vocational training. So confident is he of the potential liberalizing influence of the arts school that he declares its actual impotence to be the gravest fault of the existing university system.

Economic Position and Outlook in Germany

AN admirable review of the economic outlook of Germany, contributed by Alwyn Parker to *Lloyds Bank, Ltd., Monthly Review* of July, deserves attention not only for its sympathetic but dispassionate analysis of the present economic situation in Germany but also for its discerning attempt to understand and interpret the motives and aims of the German system. It is pointed out that the serious cleavage of outlook between the Anglo-Saxon and the German owing to the clash of strong and irreconcilable historical traditions need not be incompatible with broad and real community of aim, sentiment and policy abroad. The author traces the factors which have rendered Germany a peculiarly receptive and fertile soil for the idea of self-sufficiency. Scientific workers will be interested in his critical review of the development of synthetic processes in Germany, notably his assessment of the petrol and synthetic rubber position, as well as in his discussion of the raw materials situation. In regard to rubber, he ventures the opinion that the large-scale substitution of a costly State-subsidized synthetic product for a cheap imported material must cause some abrasion of Germany's capital resources. The greatest interest of this survey lies not in its technical details but in its attempt to understand the German mind, its plea for fair-mindedness and its attempt to forecast the lines of understanding. The author indicates certain steps that the German Government could well take of itself, but while he obviously is unimpressed with Germany's legal or economic case for the return of her colonies, he emphasizes the value of some moderate colonial settlement and the opportunity for the best qualities of philosophic statesmanship and vision. This plea for impartial investigation and goodwill should not be overlooked by any who are concerned with re-establishing an international order in which Anglo-German friendship must find its place.

American Museum Meteorite Collections

DR. CHESTER A. REEDS gives in *Bull. Amer. Mus. Nat. Hist.* (1937) a detailed catalogue of the meteorites contained in this collection, which in 1935 was transferred from the Department of Geology to that of Astronomy, and is now housed in the new planetarium building. The previous catalogue, by Dr. E. O. Hovey in 1896, showed 45 specimens representing twenty-six falls. The collection now contains 3,744 specimens, representing 546 of the 1,073 falls known to the end of the year 1935. The large number of specimens is partly accounted for by 2,129 stones, ranging in weight from 0.2 to 6,850 grams, from the Holbrook, Arizona, shower of 1912. Notable masses are the three Cape York, Greenland, siderites, the largest of which weighs $36\frac{1}{2}$ tons, that is, short tons of 2,000 lb., and is by far the largest meteorite preserved in a museum; and the Willemette, Oregon, siderite of 14.2 metric tons. Much of the general information in the catalogue, even that relating to American meteorites, is reproduced word for word from the late Dr. G. T. Prior's British Museum catalogue.

Mining Industry of Canada

THE Department of Mines of the Dominion of Canada has issued as usual its report for the Fiscal Year ending March 31, 1936 (Ottawa: King's Printer, 1936. 25 cents). This is a valuable paper and deserves careful study, especially the opening pages signed by Charles Camsell, Deputy Minister of Mines, which give a brief review of the whole mining industry of Canada; of course, the record of the gold industry is exceptionally important owing to the increased price of gold, but the base metals, copper, lead and zinc, also improved and played an important part in the increased value of the exports of base metals. This opening chapter is followed by fuller accounts of the various divisions included under mines, such as mineral resources, ore dressing and metallurgical, fuels and fuel testing, etc.

Centenary of Van der Waals

IN commemoration of the birth of J. D. v. d. Waals on November 23, 1837, an international conference on interaction between molecules will be organized by the "van der Waals Fonds" and the "Nederlandsche Natuurkundige Vereniging". The ordinary sessions will be held in the van der Waals Laboratorium at Amsterdam on November 25 and 26, and an official celebration will take place on November 27. The object of the conference is to give a survey of some of the recent work connected with the ideas of van der Waals forces. The programme will be published later. Sufficient time will be left for general discussion. A special number of *Physica* will appear during the conference; it is hoped to be able to publish in this issue a number of papers on a variety of questions having some relation to the work of van der Waals. Physicists willing to contribute to it should send in their manuscripts before October 15, and though it will be impossible to read all these papers during the conference, it is hoped

that they will play an important part in the discussions. The organizing committee, comprising Prof. J. D. v. d. Waals, Dr. A. Michels, Prof. Dr. J. A. Prins and Dr. H. B. G. Casimir, van der Waals Laboratorium, Nieuwe Achtergracht 129, Amsterdam (C), will be glad to give further information.

Solvay Conference

THE Institut International de Chimie Solvay has issued personal invitations to its sixth chemical conference, which is to take place in Brussels on October 4-9, the chosen subjects for discussion being vitamins and hormones. Eight main papers have been promised, namely: P. Karrer, a general report on vitamins; H. von Euler, carotenoid and B₂ vitamins; Ad. Windaus, vitamins D and B₁; W. N. Haworth, ascorbic acid; A. Szent-Györgyi, physiological and therapeutic properties of the vitamins; L. Ruzicka, a general report on hormones; E. Laqueur, sex hormones; T. Kógl, vegetable hormones. Including those named, some twenty-five of the leading workers in these subjects have accepted invitations, so that very valuable discussions should take place during the eight sessions.

Announcements

THE Harben Lectures for 1937 will be delivered in the Lecture Hall of the Institute of Hygiene, London, on October 11, 12 and 13 at 4.30 p.m. by Prof. E. C. Dodds, Courtauld professor of biochemistry in the University of London, on "The Theoretical and Practical Significance of Endocrinology".

THE third National Coal Convention will be held at Harrogate on October 6-7, when the speakers will include Lord Horder and Sir Frederick Sykes, chairman of the Miners' Welfare Committee.

THE Lilienthal Society of Aviation, founded in 1936, will hold its annual congress at Munich on October 12-14, when there will be an exhibition relating to aviation. Further information can be obtained from the general secretary of the Society, Wilhelmstrasse 148, Berlin, S.W.68.

THE ninth International Congress on Psychotherapy will be held in Copenhagen on October 2-4. Prof. C. G. Jung of Zurich and Dr. Paul Bjerre will give the inaugural addresses. The chief subjects for discussion will be psychotherapy in general practice and "Can Psychotherapy be Taught?" Further information can be obtained from the general secretary, Dr. Olaf Bruel, 2 Amagertorv, Copenhagen K.

A SESSIONAL meeting of the Royal Sanitary Institute will be held on October 1 in the Town Hall, Llandudno, when Dr. D. A. Powell, principal medical officer of the King Edward VII Welsh National Memorial Association, will open a discussion on "Tuberculosis in Wales—a Stock taking", and Dr. R. W. Dodgson, director of the Ministry of Agriculture and Fisheries Shellfish Services, will speak on the Conway mussel purification tanks. On October 2 a visit will be paid to the Conway Station for a demonstration and inspection of the tanks. Further information can be obtained from the Secretary, Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 550.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Investigation of Equilibrium Diagrams of Ternary Alloys by X-Rays

It is the purpose of this note to point out how rapidly and efficiently ternary equilibrium diagrams may be elucidated by means of X-ray analysis. In a recent paper, Jette¹ described a partial analysis of the chromium-iron-silicon system by X-rays. We have carried out the analysis of several ternary diagrams which will be published shortly. As an example, we give the diagram for the copper-nickel-aluminium system, the compositions being represented in the usual way by points within an equilateral triangle. Any one such diagram shows the phases at a given temperature, and a series of such diagrams is required to represent the state of affairs at different temperatures. The present diagram actually shows the phases present after a uniform heat treatment of slow cooling at 10° C. per hour. No claim is made that equilibrium has been established, our main object being to show the exploratory power of X-ray analysis. It will be supposed that the binary equilibrium diagrams, represented by the three sides of the triangle, have previously been established by metallurgical or X-ray methods. It is our experience that the investigation of the whole interior of the ternary diagram is, in general, easier than that of a single complicated binary system, since for the most part the phases are the same as those of the binaries. In other words, the appearance of quite a new phase is comparatively rare; we merely have to determine how far the two-component phases extend into areas of the ternary diagram.

The power and rapidity of the X-ray methods are due to the large amount of information which can be obtained from each powder-photograph of an alloy. The extent of this information makes it possible to explore the whole area by making up a relatively small number of alloys, judiciously chosen so as to fix the important feature of the boundaries. An X-ray photograph tells us:

(a) The number of phases present, which may be one, two, or three in a ternary diagram.

(b) The type of each phase, that is, face-centred cubic, body-centred cubic, 'γ' structure, etc.

(c) The lattice spacing of each phase, which in most cases makes it possible to deduce the compositions of the separate phases in a two-phase or three-phase area.

(d) The relative amounts of the phases present, deduced from the relative intensities of their lines

in the photograph. In addition, the presence of superlattice lines can be detected.

The ternary diagram CuNiAl is shown in Fig. 1. It is divided into single-phase, two-phase and three-phase areas. The single-phase areas have curved

FIG. 1

boundaries. The two-phase areas are covered by 'tie lines' (not shown in the diagram though their general direction can be guessed from the straight-line boundaries of the areas). An alloy of composition represented by a point in a two-phase area breaks up into two phases of compositions represented by the ends of the tie-line running through the point from one single phase area to another. The three-phase areas are triangles, the vertices of which are at cusps on single-phase areas. An alloy anywhere within a three-phase area breaks up into three phases of the compositions represented by the vertices. The diagram exemplifies these points.

Nomenclature presents some difficulties². We have tentatively called all face-centred cubic phases 'α', body-centred 'β' and γ-type 'γ'. Superlattices are denoted by suffixes, for example, α₁, β₁. Phases only appearing with three components are denoted by Greek letters from the end of the alphabet, for example, τ, which checks with the phase found by

Bingham and Haughton³. The γ phases in the CuAl system are of several types, which cannot be shown separately on the present diagram.

We have made such investigations of the FeNiAl, CuNiAl and CuFeAl systems, and are investigating the FeCuNi system. These form ternaries from the four faces of a *quaternary tetrahedron*, and it is already possible to see the general nature of the equilibrium diagram for the quaternary system FeNiAlCu. There are indications of very interesting general features of these diagrams, in particular the effects of electron-atom ratio⁴.

We are indebted to Prof. W. L. Bragg for his kind interest in this work.

New Observations on Responses to Colours in Egg-laying Butterflies

It has previously been shown¹ that hungry cabbage butterflies give a specific response, "spontaneous feeding response", on red, yellow, blue and violet papers, but not on green, bluish green or grey of any shade between black and white. Whether the insects confused green and bluish green with grey could not be investigated as they could not be trained on these colours.

Fig. 1.

I have now found another specific response to colours which makes it possible to investigate this point. As in several other species of butterflies² the female cabbage white, *Pieris brassicae* L., during egg laying will fly to leaves of various plants and on their surface perform what I have called a "drumming reaction". This reaction consists in a very quick alternating movement of the first pair of legs. It can be elicited by any object which shows certain colours. As it cannot be confused with the feeding response, it has been used as a basis for a new series of experiments on colour vision.

In every experiment, fifteen small models, cut out of grey papers of several different shades, and of coloured papers belonging to the twenty-four

Standard Ostwald papers, were offered simultaneously. All the grey papers were entirely neglected. The results for the coloured papers are shown in two curves (Figs. 1 and 2). In Fig. 1, the colours from yellow to blue, according to their position in the spectrum, are plotted against the relative number of drumming reactions on each colour.

Fig. 2.

It can be seen that the butterflies in the stage of egg laying very distinctly select a continuous range from "Emerald Green" (Ostwald No. 22) to "Oxide Blue" (Ostwald No. 16) which is slightly greenish; whereas yellow and pure blue are practically neglected. This shows that they were able to distinguish this range of colours—the greater part of which had been neglected by the same insect when seeking food—from grey as well as from yellow and pure blue. The definite distinction between yellow and green was surprising, because these two colours are confused by most insects, especially the hive bee³. Thus the humming bird hawkmoth, which during egg laying is attracted by green, visits yellow as well, but neglects bluish green⁴. Exactly those bluish green papers which by most insects are constantly neglected, or even confused with grey⁵, proved to be most attractive to the female cabbage white. This is a new proof that the system of colour vision in *Pieris* must be entirely different from that in the hive bee and most other insects, and nearer to that of man.

Fig. 3.

COLOURED DISKS WITH GRAY STRIPES (STIPPLED) OFFERED TO INSECTS

Another observation also supports this suggestion. Fig. 2 shows the relative number of drumming reactions on the Ostwald papers beyond yellow and blue. It was surprising to find among these colours a distinct though comparatively small peak in purple (Nos. 9 and 10). A more careful observation of the drumming on purple, however, showed that about half the reactions were performed on the adjacent background, which never happened when the insects drummed on green or bluish green. This raised the suggestion that for the eyes of the cabbage white, as for those of man, the purple colours might induce a greenish colour in their surroundings by a simultaneous colour contrast. (For the eyes of the hive bee, purple seems to induce a yellowish colour⁶.)

To decide this question, in a second series of experiments much bigger models were used, which made it easier to see the exact place of the drumming. Moreover, these models had been furnished with a few small colourless stripes (see Fig. 3) which for our eyes showed an especially strong contrasting colour. In an experiment where two green disks (No. 22 and 21) and two purple disks (No. 9 and 10), each of six inches diameter, were offered simultaneously, the result was as follows:

	Number of drumming reactions on:			
	Coloured disk	Adjacent background	Colourless stripes	Total
Green	48	2	0	50
Purple	0	6	9	15

This provides very suggestive, if not conclusive evidence, that, for the eye of the cabbage white, on the colourless areas adjacent to purple, one of the greenish colours which elicits a distinct drumming reaction had been induced by a simultaneous colour contrast.

Photo-labile Pigments of the Chicken Retina

THOUGH visual purples of the retinal rods have been known for sixty years^{1,2}, nothing has been learned directly of analogous substances in the cones. In the chicken retina, which contains principally cones, attempts to identify photo-labile pigments heretofore have failed³. I have extracted from it two such pigments.

Retinas of ten 8-week old dark-adapted chickens, prepared in very dim red light, are ground immediately in 4 c.c. of 3 per cent sodium chloride and 2 per cent digitonin in water. This mixture is centrifuged after about eight hours in the dark at room temperature. Spectra of a 1 cm. layer of the extract are recorded photo-electrically.

The extract is light orange in colour and possesses a complicated spectrum. On irradiation with deep red light (above 650 mμ), its extinction falls between about 470 and 700 mμ, maximally at about 575 mμ, and rises below about 430 mμ. Sufficiently long irradiation completes these changes. The final difference in extinction between the unbleached and bleached preparations ('difference spectrum') is shown in Fig. 1 A. I believe it to represent the photo-labile pigment of the cones.

When red light produces no further effect, the residue is exposed to bright white light. The extinction now falls between about 435 and 620 mμ, maximally at about 508 mμ, and rises below about 430 mμ. The difference spectrum of this change is shown in Fig. 1 B. It is characteristic of rhodopsin^{4,5}.

If retinas are soaked in 4 per cent alum for several hours following dissection, their digitonin extracts yield the difference spectrum of rhodopsin alone. The alum treatment apparently renders the cone pigment

insoluble. An extract of chicken retinas with 2 per cent disodium phosphate, freezing and thawing several times during extraction, displayed no measurable trace of either pigment.

The rise in absorption below 480 mμ on irradiation shows the cone pigment, like rhodopsin⁴ and porphyropsin—the visual purple of certain freshwater fishes⁴—to bleach to coloured products. Its difference spectrum, therefore, may partly resemble, but obviously is not, its true absorption spectrum.

Rhodopsin, porphyropsin and the cone photopigment form a graded series, in which functions and properties run closely parallel. Their colours are respectively red, purple and apparently violet. I propose to call the cone pigment *iodopsin* (iov = violet).

Fig. 1.

CHANGES IN EXTINCTION OF CHICKEN RETINAL EXTRACT DUE TO (A) IRRADIATION WITH RED LIGHT, AND (B) SUBSEQUENT IRRADIATION WITH WHITE LIGHT. BROKEN LINES SHOW HONIGSMANN'S MEASUREMENTS OF SPECTRAL SENSITIVITY OF (C) LIGHT-ADAPTED, AND (D) DARK-ADAPTED CHICKENS.

The positive portion of the difference spectrum of rhodopsin resembles the sensitivity of the rods to light of various wave-lengths⁶ (sensitivity here is the reciprocal of the minimum energy needed to evoke a constant response). A similar relation has been inferred to exist between known spectral sensitivities of cones and the spectra of hypothetical cone photopigments^{7,8}. Honigsmann⁷ has measured the spectral sensitivity of light- and dark-adapted chickens. His data, plotted as percentages of their maxima, are shown in Fig. 1 C (light adapted—cone function) and Fig. 1 D (dark adapted—rod function). Light adaptation shifts the maximal sensitivity from about 520 to about 580 mμ. This is the familiar Purkinje effect, for which clearly the extracted photo-pigments form an adequate chemical basis.

The difference spectra of rhodopsin and porphyropsin are nearly symmetrical in form⁹, while that of iodopsin is decidedly skew, due to stronger absorption on the short wave-length side of its maximum. In this spectral region the visual sensitivity might be expected to be correspondingly high. However, this is also the region in which the effectiveness of light entering the chicken cones is decreased through absorption by carotenoid filters¹⁰. The net result is the nearly symmetrical sensitivity function shown in Fig. 1 C.

Trichromatic vision in man may depend upon the presence in the cones of three distinct photo-labile pigments, differing in absorption characteristics¹. In the chicken retina three groups of colour filters provide a possible basis for hue differentiation. It is unnecessary, therefore, to assume more than a single cone photo-pigment in this animal.

Hæmodynamic Factors in the Uterus during the Latter Part of Gestation

ACCORDING to the data of Barcroft, Herkel and Hill¹, a critical change takes place in the rate of blood flow through the uterus of the rabbit after the twenty-second day of pregnancy. The rate of flow diminishes approximately one third between this and the twenty-fifth day, although it increases again by the twenty-seventh day of gestation. In an earlier paper by Barcroft and Rothschild², measurements were made of the volume of blood contained within the maternal vessels of the uterus on different days of pregnancy. The data of this study show that the volume of blood increases to a maximum by the twenty-eighth day and diminishes by fifty per cent during the next two days. The volume of the placental tissues during this time follows a parallel curve, so leading these investigators to the reasonable conclusion that the volume of blood in the uterus increases as the extent of the placental vascular bed increases. The cause of the changes in the rate of blood flow through these vessels has not, however, been described. When the foregoing data were used to estimate the efficiency of the uterine circulation during the latter part of gestation as certain growth changes take place, an insight was gained into some of the hæmodynamic factors operating at this time, providing a basis for interpreting the effects which Barcroft and his associates have reported.

The percentage of the blood volume which changes each minute (that is, the efficiency of the maternal circulation in the uterus) has been calculated from the data cited above with the result shown in the accompanying table:

Day of pregnancy	Blood volume of uterus	Minute-volume of blood	Efficiency (% turn-over)
14	80.0 cc	5.0 c.c./min.	62.5
18	12.5 "	13.5 "	109.7
20	14.5 "	20.0 "	137.1
22	16.2 "	29.0 "	179.0
25	21.5 "	19.0 "	88.3
27	29.0 "	27.5 "	94.8
28	32.0 "	28.5 "	89.0

Here, it will be seen, a marked increase takes place in the turn-over of the blood each minute until the twenty-second day, as the blood volume increases coincidentally. By the twenty-fifth day a marked decrease occurs in the efficiency of the local circulation. This fall parallels that which takes place in the circulation rate. From this point on, so far as the data go, this level of efficiency in the uterine circulation is maintained. The level at this time equals that found on the seventeenth day of pregnancy when the embryos are almost inappreciable in size, whereas by the twenty-fifth day they are comparatively large and are growing at a nearly maximum rate³. The oxygen requirement of the embryos is met by greater oxygen unsaturation of the blood as it flows through the uterus⁴.

The significance of these considerations is shown by the recent discovery that a critical change occurs in the relationship between the rate of growth of the uterus and the growth of the products of conception about the twenty-second day of gestation. Between the twenty-second and the twenty-fourth days the uterus commences to grow less rapidly, from causes already described^{5,6}. At the same time, the products of conception grow at a rate almost as rapid as at any time during pregnancy^{3,4}. The foetuses and their associated structures must act, therefore, as an impeding influence to the maternal circulation and so serve as a factor which diminishes the quantity of blood flowing through the maternal vessels of the uterus at this time. This resistance to the local flow of blood in the maternal circulation of the uterus is transient, however, as shown by the data of Barcroft, Herkel and Hill.

It is therefore clear that the rate and efficiency of the blood flow in the maternal circulation of the uterus are adversely affected as the influence of distention first becomes manifest, but with increasing degrees of distention as pregnancy nears term, some compensating adjustment takes place which maintains the efficiency of this local circulation of blood. The pumping action of the increasing muscular movements which are known to take place at this time⁷ would serve such a purpose. The efficiency and forcefulness of these contractions would likewise be enhanced by the increasing distention resulting from the disproportion in the rates of uterine and foetal growth respectively.

These considerations suggest, therefore, that the increasing distention which the uterus undergoes in the latter part of gestation first brings about a diminution in the efficiency of the maternal circulation through the uterus. As the degree of distention becomes greater, however, it becomes *pari passu* the means by which the efficiency of this circulation is maintained, mainly by virtue of the influence which distention has upon the contractility of the myometrium.

Devernalization of Spring Rye by Anaerobic Conditions and Revernalization by Low Temperature

A PREVIOUS letter in NATURE¹ presented evidence to show that in winter rye (var. Petkus) anaerobic conditions at normal temperatures (20° C.) when alternated with aerobic conditions at 1° C. quantitatively annul the vernalizing effect of low temperature. It appeared possible, therefore, that spring rye of the same variety might be devernalized by the application of anaerobic treatment at 20° C. Previous work^{2,3} has shown that the process of vernalization in winter rye decreases the number of leaves produced on the main axis before flower initiation, as well as decreasing the period of time required to reach anthesis. An increase in these characteristics in spring rye after anaerobic treatment would thus indicate a process of devernalization.

The experiment was performed by sealing the grains in tubes, with sufficient water to imbibe them fully, in an atmosphere of pure nitrogen, leaving for varying periods at 20° C., and then sowing in sand culture. Periods up to three weeks alone could be used, as longer exposures to anaerobic conditions led to death of the seeds.

The results of this experiment are given in Table 1.

Table 1.
DEVERNALIZATION OF SPRING RYE BY ANAEROBIC TREATMENT

Preliminary period in nitrogen	No. of leaves on main axis	Days to anthesis	No. of replicates
Control (none)	6.80 ± 0.20	50.3 ± 0.49	10
1 week	7.52 ± 0.11	52.6 ± 0.45	23
2 weeks	7.67 ± 0.13	54.4 ± 0.73	24
3 weeks	8.29 ± 0.35	57.4 ± 1.7	7

A significant increase in leaf number and time to anthesis follows anaerobic treatment, thus establishing the possibility of devernalization at normal temperature.

The process of vernalization is held by us to be a specific effect of low temperature, and in confirmation of this view it has been established that spring rye partially devernalized by anaerobic conditions may again be vernalized by subsequent exposure in air to 1° C. The data are given in Table 2.

Table 2.
REVERNALIZATION OF SPRING RYE AFTER ANAEROBIC TREATMENT
All variants, except controls, received 3 weeks' chilling at 1° C. in air after removal from anaerobic conditions.

Preliminary anaerobic treatment	No. of leaves on main axis	Days to anthesis	No. of replicates
Control (none)	6.80 ± 0.20	50.3 ± 0.49	10
1 week	—	47.3 ± 0.34	14
2 weeks	7.10 ± 0.23	50.5 ± 0.79	10
3 weeks	All plants failed		

It will be noted that both leaf number and time to anthesis have been reduced to the level of the controls which were untreated.

These results thus add further evidence for the reversible nature of the vernalization process.

Artificially Prepared Visible Paracrystalline Fibres of Tobacco Mosaic Virus Nucleoprotein

A RECENT letter in these columns¹ contained photomicrographs of mesomorphic or paracrystalline fibres of tobacco mosaic virus which had formed spontaneously in clarified juice expressed from diseased tobacco leaves. Similar fibres have now been prepared from solutions of the pure virus protein by suitably adjusting the pH value of the medium and the salt and virus concentrations. Although the fibres may be produced over a relatively wide range of pH values, the best results are obtained at a pH value of about 5 (near to the point where, in the comparative absence of salts, virus solutions are most viscous or gel-like).

The pure virus was obtained by a combination of precipitation with 15 per cent ammonium sulphate solution at pH 7 with isoelectric precipitation from acetate buffers at pH 3.4 as previously described². A suitable salt concentration is provided by 0.4 M ammonium sulphate. The fibres formed under these conditions have the same dimensions and properties as the fibres previously described¹, except that they are frequently more easily broken up.

Spontaneously formed fibres, when separated and dissolved in water, give a solution containing no visible ($\times 1000$) particles, but by adjusting the pH value and salt concentration the long flexible paracrystalline fibres are re-formed. Samples of pure virus protein prepared from spontaneously formed fibres, from artificially formed fibres or prepared in the ordinary way, contain (on a dry weight basis) the same percentage nitrogen (16.6) and phosphorus (0.5), and when diluted to one part by weight in a million give comparable numbers of primary lesions on *Nicotiana glauca* leaves.

The temperature at which artificially formed fibres disrupt is the same as for the spontaneously formed ones. Taken in conjunction with the evidence presented in the previous letter¹, there can be no doubt of the identity of the fibres with the virus.

Bernal and Fankuchen³, by means of X-ray analysis, deduced the arrangement of the virus molecules within the paracrystalline aggregates. They point out that in view of this structure, homogeneity of the aggregates is less certain. I assume that by this they mean that viruses like yellow tobacco mosaic, a closely related mutant strain of ordinary mosaic virus, may form a part of such aggregates without altering the general arrangement. This is a possibility which cannot be overlooked. However, my preparations were derived from plants which had been artificially infected with virus separated at its iso-electric point of pH 3.4, and which had been raised in an isolated compartment of an insect-proof glasshouse and showed no symptoms other than those of ordinary mosaic.

The finding of Bawden and Pirie⁴ that the virus contains nucleic acid has been confirmed, and my preparations contain 0.52 per cent phosphorus. There is evidence to associate the acid prosthetic groups deduced by me⁵ on the basis of the pH activity curve for this virus, with the nucleic acid demonstrated by Bawden and Pirie. The circumstance that Stanley's⁶ earlier preparations contained no demonstrable amounts of phosphorus, and the presence of small but variable amounts in his later preparations⁷ are understandable when it is realized that during the purification processes his preparations were exposed to pH values which are known to

inactivate a large percentage of the virus, and that this action must have been more pronounced in his earlier methods. The test for active virus is much more sensitive than the test for phosphorus.

Blood-groups of Veddahs

BLOOD-GROUPING in the field in Ceylon presents almost insurmountable difficulties, so that no records of blood-grouping of the Veddahs have been hitherto published. Until recently I had only one record—that of a Veddah whom I had persuaded to come down to Colombo for treatment in hospital. Recently, however, I had the opportunity of making observations on a series of four more Veddahs. These were brought to Colombo, with two others, who refused to give blood, by an enterprising showman, for exhibition at a fair held on the occasion of the Coronation celebrations. All the Veddahs were tolerably good specimens of their race. The blood samples were examined independently by myself and by the staff of the Pathology Department, General Hospital, Colombo, with identical results. I used imported standard sera (Burroughs and Wellcome's) that had been kept in the refrigerator. The hospital authorities make their own standard sera. Although the numbers examined are too few for any definite conclusions to be drawn, I consider they are worthy of record in so far as no previous information is available relative to this important race.

TABLE I BLOOD-GROUPS OF VEDDAHs

Veddah No.	Name	Sex	Locality	Blood-group
1.	Davitha	♂	Buhgabadena Bintenno	B
2.	Kaira	♂	Dambana Bintenno	O
3.	Burunda	♂		B
4.	Kanda	♂		O
5.	Dematha (son of No. 4)	♂		O

These results give a proportion of 60 per cent Veddahs with the O group and 40 per cent with the B group. The proportion of O is thus practically the same as in the Australian aboriginal, but the B group differs considerably in the two races. On the contrary, the Paniyans of South India agree with the Australians in the low proportion of B, but differ from both Australians and Veddahs in the low proportion of O. The difference is made up by a high proportion of group A (see Aiyappan, 1936¹).

With regard to the other inhabitants of Ceylon, I give below the results of a series of blood-groupings which have been taken in the General Hospital, Colombo, for routine blood-transfusion purposes, and for which I am indebted to Dr. S. Thiagarajah, the pathologist to that institution. It will be noted that, in all the communities studied, group O takes the

highest place, except in the Moors, where groups O and B are in equal proportion. Group B is also high in the Tamils, so that the high value of that group in the Moors is to be explained by the amount of Tamil blood present—a fact which is corroborated by their physical characters. The Sinhalese, on the contrary, have an almost equal proportion of individuals with groups A and B blood. The Veddahs, therefore, so far as the meagre numbers examined throw any light upon the question, do not resemble either of the predominant local populations, but fall into a category of their own. Examination of larger numbers would most probably bring them into line with the Australian aboriginals, a supposition which would be expected on the grounds of their physical characteristics.

TABLE II. BLOOD-GROUPINGS OF OTHER CEYLONIAN PEOPLES.

People	Numbers examined	Group O	Group A	Group B	Group AB
Sinhalese	712	335	187	176	14
Tamils	136	69	19	42	6
Burghers	61	35	17	8	1
Moors	29	10	7	10	2

TABLE III. PERCENTAGE REPRESENTATION OF BLOOD-GROUPS IN THE PEOPLES DISCUSSED HEREIN.

People	Group O	Group A	Group B	Group AB
Veddahs	60	—	40	—
Paniyans	20	60	7	10
Australians	57	38.5	3	1.5
Sinhalese	47	24.7	23.1	2.0
Tamils	50.7	14	30.9	4.4
Burghers	57.4	27.7	13.1	1.6
Moors	34.4	24.1	34.4	6.8

In conclusion, I have to acknowledge my indebtedness to Prof. F. O'B. Ellison of the Physiology Department, Ceylon Medical College, and his laboratory staff for the use of apparatus in his department.

Modes in Modern Egyptian Music

WE have been engaged on determining the frequency ratios involved in the principal musical scales or modes in current use in Egypt to-day. These scales were the subject of a controversial discussion at an international congress held in Cairo in March 1932.¹

In the present investigation, three expert tuners (appointed by the Royal Institute of Oriental Music) tuned a Qanun, an instrument consisting of strings stretched on a sounding board, to the different modes, and the frequencies were then measured by means of an audio-frequency valve oscillator to which a calibration curve was plotted by means of a set of standard tuning forks. The actual determination of each frequency was carried out using the method of beats. The notes constituting each scale were taken in ascending and then in descending order, so as to

correct for possible variation in temperature. The experimental error is of the order of 0.1 per cent.

The results for each of the three tuners were recorded separately and an average was then taken. The following table gives the fourteen recognizable intervals into which an octave was found to be subdivided compared with the diatonic and equitempered scales.

The four principal modes correspond to the following groups of notes (quoted by their numbers): (1, 3, 5, 7, 9, 11, 13), (3, 4, 8, 9, 11, 13, 1'), (3, 5, 7, 8, 11, 12, 1'), (1, 3, 4, 7, 9, 10, 14). Of these the last is the same as the minor scale in European music.

No. and Name of Note	Frequency ratios		Equi-tempered scale	Diatonic scale	Symbol
	Our results	Confinee results			
1 Rast	1	1	1	1	C
2 Shahnax	1.067	..	1.067	1.043	C#
3 Doka	1.123	1.123	1.120	1.090	Db
4 Kurd	1.200	..	1.187	1.125	D
5 Sika	1.238	1.237	..	1.171	D#
6 Nim Buzalk	1.274	..	1.257	1.200	Eb
7 Ghika	1.330	1.337	..	1.237	E
8 Higas or Saba	1.417	..	1.411	1.302	Fb
9 Nawa	1.496	1.503	1.496	1.333	F
10 Hissar	1.590	..	1.583	1.390	F#
11 Husnini	1.685	1.685	1.677	1.440	Gb
12 Agam	1.779	..	1.778	1.500	G
13 Irak	1.831	1.838	..	1.562	G#
14 Nim Mahur	1.880	..	1.882	1.600	Ab
1' gawab el Rast	2.000	2.000	2.000	1.647	A
				1.738	A#
				1.800	Bb
				1.875	B
				1.920	Bb
				1.955	B#
				2.000	C

Other modes are obtained by changing the first note (key-note) in a group. The most characteristic feature of the scheme is the appearance of neutral thirds and neutral sevenths.

A fuller account will appear elsewhere.

Magnetic Anisotropy of Rare Earth Sulphates and the Asymmetry of their Crystalline Fields

IN an important paper in the *Physical Review* for 1932 Penney and Schlapp¹ have discussed theoretically the Stark-splitting of the energy levels of the rare earth ions in crystals under the influence of the crystalline electric fields, and its influence on the magnetic behaviour of the ions. Experimentally, Spedding and his co-workers² have studied the absorption spectra of rare earth salts of the type $M_2(SO_4)_3 \cdot 8H_2O$, where $M = Pr, Nd, Er$ at different temperatures, and thence deduced the low-lying energy levels of the M^{+++} ions in the crystals. They find that (1) the number of low-lying energy levels and their relative separations are the same as predicted by the theory for a field of cubic symmetry

acting on the M^{+++} ions; (2) the intensity of the cubic field required to produce the observed separations is the same in all the three crystals, as should be expected from their isomorphism; (3) the observed separation of the levels is not inconsistent with the available magnetic data for the mean susceptibilities of the crystals. From these and other results, it has been concluded that the fields acting on the M^{+++} ions in these crystals should be almost rigorously cubic in symmetry.

One direct result of such a cubic symmetry in the field would be a magnetic isotropy for the crystal, and any observed deviation from isotropy will give us some idea of the deviation of the field from cubic symmetry. We have recently measured the principal magnetic susceptibilities of single crystals of several rare earth salts, and we give below the values for the anisotropy of the sulphates; $\Delta\chi$ denotes the difference between the maximum and the minimum principal susceptibilities of the crystal, and χ the mean of the three principal susceptibilities.

Crystal	$\Delta\chi/\chi$
$M_2(SO_4)_3 \cdot 8H_2O$	
$M = Pr$	0.20
Nd	0.11
Sm	0.21
Er	0.12

$\Delta\chi/\chi$ is not small, and when we remember that the group of atoms associated with each M^{+++} ion in the crystal should have at least this anisotropy, and has very probably more (as the different groups present in the unit cell of the crystal—probably eight in number—will not, in general, be oriented parallel to one another) and that it is the anisotropy of the above group (and not that of the crystal) which corresponds to the asymmetry of the field under consideration, it is easy to realize that the deviation from cubic symmetry should be quite marked. From an inspection of the table it becomes clear, as pointed out by Penney and Kynch³, that the non-cubic part of the field has produced separations in levels, degenerate in the cubic field, comparable in size with those of the cubic field pattern itself.

A rediscussion of the valuable results on the absorption spectra of these crystals obtained by Spedding and his co-workers, taking into account the non-cubic nature of the crystalline fields as evidenced by the magnetic anisotropy of the crystals, is very desirable.

Variations of Cosmic Ray Intensity during Magnetic Storms

IN a paper¹ on trajectories of electric particles with applications to cosmic rays, published January 4, 1937, I directed attention to possible effects of magnetic storms in the following words:

"As to other electromagnetic fields which may modify this supposition (regarding simplifying

hypotheses for the mathematical treatment), the only case of interest may be the *outer magnetic field during magnetic storms*. It would be very interesting to make a careful inspection of the cosmic ray registrations during such a storm (for instance of the order of magnitude of the storm of February 4th, 1872, when auroras were seen almost over the whole earth) in order to discover possible actions due to this field."

It is most interesting that such an effect has just been observed during the recent magnetic storms in April this year, both by Mr. S. E. Forbush in America¹ and by Prof. Victor F. Hess and A. Demmelmair in Europe².

We have here an effect analogous to the effect of magnetic storms on auroras, driving the aurora zones away from their usual situations and towards the magnetic equator as the intensity of the storm increases.

The mathematical theory of the motion of electric particles in the earth's magnetic field, which I developed³ so long ago as 1904, and which Mr. Forbush attributes to Lemaître and Vallarta, receives by these new facts renewed interest and suggests continual observations of cosmic rays both in high and low magnetic latitudes, because the solar activity and magnetic storms both approach their maximum intensity.

Points from Foregoing Letters

As an example of the ease with which equilibrium diagrams of alloys containing three elements can be obtained, by means of X-ray analysis, A. J. Bradley, H. J. Goldschmidt, H. Lipeon and A. Taylor submit a diagram for the copper-nickel-aluminium system. It shows the phases present at different percentage composition, after a uniform heat treatment (slow cooling at 10° per hour; equilibrium not necessarily established). The X-ray method gives at the same time the number, nature and relative amount of phases present and the lattice space of each phase.

Dora Ilse describes experiments on the response of egg-laying butterflies to coloured papers; these indicate that colour vision in the cabbage butterfly, *Pieris*, is different from that in the hive bee and most other insects and nearer to that of man. The cabbage butterfly in the stage of egg-laying reacted to a range of colours from 'emerald green' to 'oxide blue' and responded also to simultaneous colour contrast (green induced on white background adjacent to purple).

Dr. G. Wald has extracted from chicken retinas rhodopsin and the photo-labile pigment of the cones, heretofore unknown. The shift in visual sensitivity toward the red on light adaptation (Purkinje effect) in the chicken appears to depend upon the spectral characteristics of these pigments. The cone pigment, for which the name iodopsin is proposed, is apparently violet in colour and bleaches to coloured products.

From the data of Barcroft and his associates, Dr. S. R. M. Reynolds has estimated the efficiency of the maternal circulation of the uterus of the rabbit between the fourteenth and twenty-eighth days of gestation. It is found that the minute-volume turnover of blood in the uterus increases until the twenty-second day, after which it decreases sharply. This decrease in the efficiency of the uterine circulation is coincident with a period of diminished uterine growth and accelerating foetal growth. It is suggested that with the onset of increasing distention the uterine circulation is impeded, but as the influence of distention becomes more marked, the circulation through the uterus is aided, chiefly by the increasingly effective contractions of the myometrium which occur as gestation nears term.

Cold-treated ('vernalized') wheat grains, imbibed in water and kept in an atmosphere of nitrogen at 20° C., will survive, according to Prof. F. G. Gregory

and O. N. Purvis, for three weeks, and will become devernalized, as shown by a significant increase in the leaf-number and in the time of flowering. Partially devernalized spring rye may again be vernalized by subsequent exposure in air to 1° C.

The artificial preparation, from pure virus protein, of paracrystalline fibres of tobacco mosaic virus is described by R. J. Best. The properties of these fibres are similar in all respects to the spontaneously formed ones previously described in *NATURE*. Bawden and Pirie's demonstration of the presence of nucleic acid in the virus molecule has been confirmed.

Blood examination of five Veddahs from Ceylon, reported by Prof. W. C. O. Hill, showed two of them to belong to the blood-group B and three to blood-group O. The author believes that examination of a larger number of individuals will probably show that they are similar to the Australian aborigines. He also gives tables showing the blood-groupings of peoples from the island and the percentage blood-groups in each. In all communities of Ceylon which have been studied, group O takes the highest place, except in the Moors, where group O and B are in equal proportion.

A table is given by M. Mokhtar and Dr. A. M. Mosharafa showing fourteen recognizable intervals into which an octave, in modern Egyptian music, could be subdivided, compared with the diatonic and the equitempered scales. The notes were obtained by means of a Qanun, an instrument consisting of strings on a sounding board, and the frequencies were measured by means of an audio-frequency valve oscillator calibrated with a set of standard tuning forks.

From extensive studies on the absorption spectra of crystals of hydrated sulphates of the rare earths at different temperatures, Spedding and his co-workers have concluded that the crystalline electric fields acting on the rare earth ions in these crystals should have cubic symmetry. Prof. K. S. Krishnan and A. Mookherji now report marked magnetic anisotropy of these crystals, which does not support this conclusion.

Prof. C. Störmer quotes a statement which he published last January, indicating on theoretical grounds the possibility of an interrelation between magnetic storms and the intensity of cosmic rays, which has since been observed by Forbush in America and by Hess and Demmelmair in Europe.

Research Items

Problems of the New Stone Age

SOME problems in the changed outlook of the last twenty years on the introduction and spread of the neolithic civilization into Europe have been discussed by Mr. H. J. E. Peake (*Mem. and Proc. Manchester Lit. and Phil. Soc.*, 1936-7). By 1925 it had been shown that the neolithic culture had reached Switzerland from western Asia by way of the Aegean and Danube Valley early in the third millennium B.C. The problem remained whether it reached the west in the same way or had come by sea from the eastern Mediterranean. This question must be viewed from the wider standpoint, in time and space, of when man first began to cultivate grain and domesticate animals, and how such knowledge reached our islands. Cultivation of wheat apparently began in south Syria or northern Palestine. Early grain growers are, with certain exceptions, always possessed of domesticated animals, and the precise origins of agriculture are obscure. Its progress, however, can be traced from Asia, through the Aegean to Switzerland, via the Danube. West of the Rhine, however, is a rude pottery, which has been filiated with the leather bag, derived, it is now suggested, from animal *scrota*. This 'bag-ware' is found widely distributed in western Europe, appearing in Switzerland and Germany from the west, and having as its starting point Lusitania. Important elements in this Lusitanian culture are shown to derive from the eastern Mediterranean—the tomb and the pottery. The megalithic tomb is traced back to Tell Arpachiya and thus related to the Tell Halaf culture of the fourth or fifth millennium, while it descends to the stone cist of the early Bronze Age. The evidence of the pottery depends on a number of decorative, and other details traced from the eastern Mediterranean and ultimately Tell Halaf, beginning not later than the end of the fourth millennium, and appearing in the Iberian peninsula about 2800 B.C. Cattle, which could scarcely have been brought from the Aegean, were probably acquired by contact with Danubian peasants of Switzerland. This culture passing through France reaches Britain by a land bridge from Artois, and appears as the early neolithic culture of Windmill Hill. The red "bag ware" found at Maiden Castle, on the other hand, may have reached Britain from Brittany.

South African Native Cattle

LITTLE has been attempted by Europeans in the way of improving the cattle of Africa by selection within native breeds, the practice being to intergrade with European breeds. H. H. Curzon and R. W. Thornton, realising the potentialities of the native cattle, have laid a foundation for further investigations by outlining the cattle types of Africa and their approximate distribution (*Onderstepoort J. Vet. Sci. Anim. Ind.*, 7, 613; 1936). Probably all the breeds, except the Hamitic longhorn of Egypt, came originally from Asia, and all reached their destination through north-east Africa except the shorthorned zebu which was introduced along the east coast north of the Zambezi River. Three parent stocks are involved—Hamitic longhorn, brachyceros

and lateral-horned zebu; and from these three other types have been derived—short-horned zebu, sanga, and lyre-horned zebu. In West Africa there are possibly two other types derived from admixture of brachyceros and Hamitic longhorn in one case, and in the other from brachyceros and thoracic humped zebu. The paper is illustrated by perhaps the most complete set of photographs of African cattle breeds yet published.

Stomatopoda of the Bingham Oceanographic Collection

G. ROBERT LUNZ has reported on the Stomatopoda from various localities collected by the *Pawnee* and from coastal trawlings by members of the Bingham Oceanographic Laboratory (*Bull. Bingham Oceanographic Collection. Peabody Museum of Natural History, Yale University*, 5, Art. 5; Jan. 1937). There is also included valuable material collected on the west coast of Florida by Miss M. Storey of Stanford University and a few specimens from Tahiti obtained by Mr. Henry Sears. 157 specimens are recorded, referable to five genera and thirteen species. A new variety is described from Tahiti of *Gonodactylus chiragra*, a species well known throughout the tropical portions of the Pacific and Indian Oceans but not before recorded from Tahiti, also a new variety of *Chloridella rugosa*, and there is one new species, *Chloridella edentata*, described from a single specimen, its nearest relative being *C. montoides*.

Cytology of *Gagea spathacea*

Gagea spathacea is a member of the Liliaceae occurring from southern Sweden through Denmark to Holland and Belgium. It apparently produces no seeds, its pollen is sterile and it reproduces vegetatively by numerous small bulbs. Dr. M. Westergård (*C. R. Lab. Carlsberg, Série Physiologique*, 21, No. 18), who has investigated its cytology, finds that while *G. lutea*, *G. minima* and *G. pratensis* undergo their pollen meiosis in Denmark in January, in *G. spathacea* this is delayed until April. *G. minima*, the most nearly related species, has $n=12$, while in *G. spathacea* $2n \approx 102$ and the chromosomes fail to pair in meiosis, with resulting micro-nuclei. This species is probably a hybrid; but it is not clear how its more than octoploid number of chromosomes has been reached. Its vegetative spread to Sweden must have occurred when the Baltic sea was a lake, unless it arose independently through crossing in the northern area. The embryo-sacs of *G. minima* and *G. lutea* ($n=36$) were examined, and stages were found indicating that the sac is of the type now known in *Lilium*, *Fritillaria* and *Tulipa*, that is, the four megaspore nuclei function, three passing to the chalazal end of the sac and one to the micropylar end. Here they all divide again, the chalazal spindles fusing so that two triploid nuclei result. One of the latter degenerates while the other divides. The mature sac thus contains an egg apparatus composed of three haploid nuclei and two triploid antipodal cells. In double fertilization a pentaploid endosperm arises from the fusion of a haploid and a triploid nucleus with the male nucleus.

Magnetostriction

THE June issue of the *Science Reports* of the University of Sendai, Japan, contains two reports of the Research Institute of Iron, Steel and other Metals by Dr. Y. Masuyama, which deal with his recent work on magnetostriction of iron, nickel, cobalt, single crystals of iron and binary alloys of the three metals. The specimens were ovoids placed in the centre of a magnetizing coil, the field of which could be varied from 0 to 400 gauss. The changes of length of each ovoid were determined by fixing it between two quartz tubes coaxial with it, one of which projected out of the coil and ended in a small brass block. To compensate for temperature changes of length of the ovoid, a brass bar of suitable length was placed within the coil parallel to the axis of the ovoid and between two similar quartz tubes. Between the brass blocks a thin spindle carrying a mirror was placed in such a way that differential changes of length of ovoid and brass rod produced a rolling of the spindle and rotation of the mirror. The changes of length observed are generally less than 80 millionths at the maximum field, and are shown by curves in terms of the field and of the magnetization. They are independent of the sign of the field and at low fields are different for increasing and decreasing fields. For cobalt and nickel and alloys of the two the length decreases; for iron and alloys containing iron the length decreases at first, then increases as the field is increased. Each material tested showed hysteresis in its magnetostriction, and the effect will have an important bearing on the theory of magnetization.

Structure of Diborane

AN outstanding difficulty for the valency theory is the molecule B_2H_6 , and the non-existence of the molecule BH_3 , since boron is a trivalent element in numerous other compounds. Some light is thrown on the problem by determinations of the interatomic distances by S. H. Bauer (*J. Amer. Chem. Soc.*, 59, 1096; 1937), by means of the electron diffraction method. The values for the B—B (1.86 Å.) and B—H (1.27 Å.) distances are considerably larger than the single-bond separations expected from other diatomic hydrides. This is interpreted as meaning that the bonds in the molecule have to some extent a character weaker than single bonds. This would be expected for the B—H bonds on the basis of structure I:

which gives each B—H two thirds single-bond and one third one-electron-bond character. A slight extension considering resonance to structures such as II would further account for the increased B—B distance. The distances are also compatible with a structure representing resonance among the seven arrangements:

giving each bond 6/7 single-bond and 1/7 no-bond character. Theoretical arguments support the view that the molecule resonates among all the above structures, the B—B and B—H bonds having single-bond, one-electron-bond and no-bond characters.

Shortening of the B—B distance below the single-bond value is not observed; this is regarded as eliminating all structures such as Wiberg's, which attribute some double-bond character to the B—B link. The stability of B_2H_6 relative to BH_3 is explained as due to the resonance energy made available by the full use of the four orbitals of boron.

High Intensity Light Sources

AN article by Dr. J. A. V. Fairbrother in the *Electrical Review* of August 6 discusses the light source required to project a beam within a fairly small angle. Practical considerations permit only a small source, as otherwise a large paraboloidal reflector would be required. The lower limit to the size of the light source is fixed by its brightness (intrinsic brilliancy) and the quantity of light obtainable from it. The intrinsic brilliancy is measured by the candle power divided by the projected area of the source on a plane perpendicular to the direction of view. It is convenient to measure it in candles per square millimetre. For bodies which emit full radiation the intrinsic brilliancy increases rapidly as the temperature approaches the melting point. As carbon and tungsten have the highest melting points, the carbon arc and the hot tungsten filament are the two high-intensity light sources usually employed for projection purposes. But owing to the fact that much of the spectral emission from a hot surface is not in the visible region, it is an inefficient converter of heat into light. One of the earliest light sources was the Welsbach mantle, which made use of the selected radiation from cerium and thorium. At the present time the most promising of all is the selected light emission from gases and vapours the molecules of which are excited by the passage of an electric current. By exciting mercury vapour in a quartz envelope at a high pressure, a light source is attained which has a higher efficiency and greater intrinsic brilliancy than over-run tungsten. The author has obtained with a carbon arc a maximum brilliancy of 330 candles per sq. mm. which is about eighteen times the average intrinsic brilliancy of the 5-kw. tungsten filament spot lamp. Mercury vapour quartz lamps are now being made the length of the arc of which is only about 10 mm. and which when the temperature is kept low by cooling water in contact with the outer wall of the envelope can take an input of 700 watts. This lamp approaches the carbon arc in intrinsic brilliance and is more than twice as efficient.

Sunspot Photography with a Small Visual Refractor

THIS is the title of a paper by Mr. Cecil Maby (*J. Brit. Astro. Assoc.*, 47, 9, July 1937), in which the author gives the results of his experiments with different filters and photographic plates. He made use of his telescope and its Huygenian eyepiece as projection lenses, and those who are interested in the photography of sunspots will find much useful information in this paper on the employment of visual refractors for this purpose. The paper should be studied by amateur astronomers, who will find a full description of the equipment, which is both efficient and inexpensive.

ERRATUM. The paper referred to under the heading "Petrofabric Study of Moine Schists" in *NATURE* of September 4 (p. 429) was by Dr. F. O. Phillips, Department of Mineralogy and Petrology, Cambridge, and not by F. C. Cole as stated.

Engineering and Marine Exhibition at Olympia

AT this Exhibition, which will remain open until October 2, there is so much of scientific interest that it is possible only to select a few representative items as indicative of the extent to which the results of research are being utilized with the aid of mechanical ingenuity. One gets, for example, a definite impression of a universal effort being made to deal with the problem of noise both by improvements in design and workmanship and by the adoption of new types. At one stand a noiseless sliding door is exhibited, and of silently operating machinery a notable example is the Mirrelec-Imo pump for oils and other liquids. This has only three moving parts—a central screw which is the actual pumping unit, and two side screws which act as seals and are rotated merely by their engagement with the central screw. In high-speed Diesel engines vibration is destructive of the exhaust pyrometers which, by the close relationship between exhaust temperature and horse power, are necessary to ensure that an even and efficient balance is maintained between the several cylinders. Messrs. Negretti and Zambra are exhibiting pyrometers in which a few inches of the tube immediately below the instrument have been replaced by a helical spring, and instruments so constructed are to be seen mounted on a vibrating table yet relatively unaffected.

The hygienic importance of the reduction of dust lends interest to means for its measurement, and the Tyndallometer shown by E. Leitz (London) provides a new and rapid means of its measurement. It consists of a dust chamber, a photometer head, an observation telescope and the necessary means of illumination. In the field of view is a beam of the scattered light and a comparison beam and, when these are equalized, the scale reading and the calibration curve give an instantaneous value for the dust content. On the same stand is shown a simple profile projector for the metal industry with several other optical aids. Messrs. Kelvin, Bottomley and Baird, Ltd., have on view the colour vision lantern developed by Dr. L. C. Martin in collaboration with the Medical Research Council, and also the K.B.B. Cabinet for ultra-violet fluorescence. The latter can be seen in operation with a very representative group of samples which illustrate its value in scientific testing and research, and also in industrial, medical, police and other investigations. In Messrs. Avery's recent design of Brinell and diamond impression testing machine the arrangement is such as to enable results to be obtained very rapidly, and in this respect alone this exhibit marks an advance on the usual design.

Under modern conditions, metals are frequently required to conform to very severe specifications, and Barronia Metals, Ltd., are exhibiting examples of many such problems which they have solved. One of these was the preparation of a non-ferrous alloy with a coefficient of expansion greater than steel for use with a hydrocarbon gas containing sulphur at a pressure of 200 lb. per sq. inch and a temperature of 1150° F. Other instances of new developments in manufacture of materials are the glass cloth now being made by Chance Bros. and Co., Ltd., to replace asbestos cloth in low-temperature services and likely also to develop in decorative and other directions,

and the method of electric forging which has been brought to a fine art by Messrs. Omea, Ltd. The samples of forgings exhibited indicate the wide application of the process and the high quality both of material and of surface which is obtainable. In conjunction with H. A. Brassart and Co., Ltd., Messrs. Imperial Chemical Industries Ltd. illustrate the Brassart process for acid burdening the blast furnace. By regulating the flux so as to form slag of the lowest possible melting point and viscosity, iron production is increased while less coke is used and low-grade ores can be dealt with. As a result also of the sodium carbonate treatment there is a reduction of sulphur and, due to oxidation, of silicon content. The Macrome treatment of tool steel by an electric process, applied after the usual heat treatments have been given, is claimed by Messrs. Macrome Ltd. to increase the working life of tools by 50–300 per cent according to the steel treated and the work performed. An electric process exhibited by the O.C.P. Company is that for conditioning water and preventing scale in boilers. The water is made to pass through tubes each containing an electrode, and this process effects a physical change in the mineral salts which, on being heated, appear as crystals and do not build up scale. The elimination of chemical treatment is an obvious advantage of the method.

The Marconi Company has arranged a series of historical exhibits illustrating the development of wireless apparatus. Another exhibit of this firm shows how one type of echometer can indicate to a trawler the depth of the sea-bed and also that at which a shoal of fish may be passing. The Accurate Recording Instrument Co. has working models of a liquidmeter which will very soon be manufactured. This, although very sensitive and carefully compensated, is of a robust construction and is not likely to get out of order. It operates by means of two pairs of opposed hydraulic bellows so that the displacements made in the tank are exactly reproduced at the dial. Among other recording instruments, Messrs. Radiovisor show the counting unit such as is used in the Mersey Tunnel to give a record of vehicles entering and also in factories for counting sacks, tins, etc., by the interception of a beam of light.

Of the many Diesel engines on view, that of the Brush Electrical Engineering Co. Ltd. will be of considerable interest to engineers. It is a horizontal type and has four cylinders arranged in pairs on opposite sides of the crankshaft. An independent test by Mr. W. A. Tookey showed the fuel consumption to be 0.357 lb. per B.H.P. hour when developing 250 B.H.P. at a speed of 250 r.p.m.

The exhibit, however, which takes the highest place in scientific importance and which at the same time appeals to all who are mechanically minded is that of the Department of Scientific and Industrial Research and associated bodies. It illustrates researches carried out in engineering and metallurgy, showing how the tests are made on models of ships' hulls and propellers, on coal, on the transport and storage of food and on fire resistance of structures. By the use of short films the visitor sees more than the mere instruments and materials of the test; he is enabled to follow the course and operations of the investigation.

Origin of the Red Rocks

THE subject for discussion in Section C (Geology) at the British Association on the morning of September 2 was the "Origin of the Red Beds of the Northern Midlands". Speakers, however, did not confine themselves to local conditions, and other parts of England were also considered.

In opening, Dr. R. L. Sherlock remarked that the region discussed forms an indefinite area but may be supposed to include the Cheshire Basin, the synclines between the fanning-out ridges of the Pennine Range and the easterly dipping beds of Nottinghamshire.

It is agreed that the British Permo-Trias is of Continental origin and that the climate became progressively drier from the beginning to the end of the period. This fact seems to be of almost world-wide application, for it is also true for the United States, South Africa and other countries.

Late in Carboniferous time, earth-movements on a great scale probably raised Great Britain into mountains, but rapid erosion of the soft Coal Measures soon reduced the elevation, and the detritus filled the hollows and formed red beds. This indicates oxidation of grey strata in a dry climate. There is a relation between colour and texture; the finer the grain the richer the red tint, owing no doubt to ease of oxidation. The green colour found at times appears to indicate wetter periods. Although there is no doubt that secondary changes of colour have occurred, it is highly probable that both red and green strata are primary. Evidence for the primary origin of red beds is that the colour is constant in depth. It is noteworthy that green marls occur at the top of the Keuper, just before the Rhaetian Sea burst in, when base-levelling of the land had presumably allowed wet oceanic winds to bring in a damper climate.

Although the saline deposits were no doubt deposited in drying up inland seas and lakes, the source of supply offers difficulties. Ordinary sea water, if evaporated, would deposit only 0.7 ft. of gypsum or anhydrite for each 1,000 ft. of depth, yet beds 10 ft. or more in thickness were deposited from shallow seas. Evidently there was local concentration.

Gypsum often shows swirl-like structures, and so does rock-salt. In Cheshire, stratification and cross-bedding are also present in the salt, indicating a possible explanation of the thickness of saline deposits. If evaporation caused supersaturation of the water, the salt would be deposited very rapidly and the granular precipitate might be concentrated by currents. It sometimes happens that, if two bore-records are compared, one containing thick salt and the other none, the records agree roughly if the salt is ignored, suggesting that the time of formation of the salt was negligible.

While the rest of our salt deposits were formed in desert lakes, the Middlesbrough deposits represent a dried-up sea.

Mr. F. W. Shotton communicated the results obtained by the Lapworth Club of the University of Birmingham in an investigation, lasting several years,

of the outcrops of Lower Bunter in Worcestershire and East Shropshire between Oakengates, Bewdley and Stourbridge. Every accessible outcrop was examined and careful measurements made of dip and false bedding; more than a thousand readings being taken and examined statistically. In addition, numerous rock specimens were collected and examined for variation in the size of the sand-grains. Conclusions arrived at were that, throughout the area, the Lower Bunter is false-bedded and that it was deposited on land by easterly winds coming from the Mercian Highlands. The sand is remarkably well-graded and free from clay or silt-bands, and 90 per cent lies between the ranges of 0.50 mm. and 0.10 mm.

Mr. A. N. Thomas then described the Trias of north-west Somerset between Porlock and Williton. The Triassic subsurface is highly irregular and the earliest deposits fill in isolated depressions, the later ones being increasingly widespread so that the areas tend to coalesce.

Dr. S. E. Hollingworth gave an account of some results of recent borings in the Vale of Eden. These borings have proved the presence of three horizons of anhydrite in the 'Permian' Hilton Plant Beds at Kirkby Thore, although only two horizons are known elsewhere in the area. As these chemical precipitates indicate periods of desiccation, they are probably due to regional climatic changes, and it is reasonable to suppose that sequences of such deposits in adjacent areas may be correlated. This does not necessarily mean that two areas of deposition were united. Dr. Hollingworth correlates the lowest anhydrite bed (base of Hilton Plant Beds) with the lower salt (and anhydrite) at the base of the 'Permian Middle Marl' of the region east of the Pennines. The two higher horizons of the Vale of Eden he correlates with the upper salt and anhydrite and the upper anhydrite respectively of Yorkshire. Correlations between Cumberland and Furness indicate the probability of a lateral passage from 'Permian' Hilton Plant Beds to 'Triassic' St. Bees Shales. Dr. Hollingworth's conclusion is in accordance with the evidence from the east of the Pennines of a lateral passage of 'Permian' into 'Trias' brought forward in 1911 by Dr. R. L. Sherlock.

No time was left for discussion, but inquiries were made as to where the formation of red beds in Continental areas is at present in progress. This difficulty is analogous to that felt by students of coal formation—the origin of which by swamp-growth is generally agreed upon, although the exact conditions for it do not seem to exist anywhere at the present day. Nevertheless, in various parts of the world certain kinds of Triassic-like rocks are being formed, for example, in Turkestan, although nowhere can all the types be found now forming.

As was pointed out by Dr. Rudolf Richter on another occasion, when describing conditions of sedimentation off the German coast, we must not carry uniformitarianism too far; special conditions existing at certain periods have never been repeated.

R. L. S.

The Teaching of Mathematics

THE mathematical subsection (A*) of the British Association departed this year from its usual policy of presenting papers on specialized branches of research, and its sessions at Nottingham were devoted chiefly to two discussions on the teaching of mathematics. On Saturday, September 4, Prof. E. H. Neville opened a discussion on the unification of algebra in schools. Mr. T. A. A. Broadbent condemned the older school text-books as a collection of watertight compartments, and pointed out the need for the course to be systematized and unified. Mr. G. L. Parsons contrasted the older method of putting all the emphasis on technique with the newer methods of bringing out the ideas of the subject. He favoured the approach by means of the formula or the equation rather than by tedious drill in elementary algebraic processes. Mr. M. H. A. Newman gave the university point of view, particularly as regards the importance of linear transformations and matrices. Mr. W. J. Langford pointed out that changes in the school course could not be made unless such examinations as that for the School Certificate were modified correspondingly. He suggested that teachers should agree upon a policy, and then submit alternative syllabuses to the examination authorities.

The papers attracted a large audience, including many from other sections, and the lively discussion that ensued proved that the subject was felt to be of great interest and importance.

On Tuesday, September 7, Prof. H. T. H. Piaggio opened a discussion on the bearing of higher geometry on the school course. Prof. E. H. Neville protested against the policy of drill in the application of devices of which no rational explanation had been given. Mr. H. G. Green showed how to give this explanation in the case of the 'line at infinity', and Prof. W. H. McCrea in the case of the 'circular points at infinity'. Prof. H. S. Ruse pleaded for an extended treatment of differential geometry, including vector methods. A general discussion followed.

At the end of this discussion Mr. C. H. H. Franklin exhibited a most interesting collection of models representing four- and five-dimensional solids, by a principle analogous to that employed to represent three-dimensional solids by a sketch on two-dimensional paper.

The secretary of the subsection, Dr. Dorothy M. Wrinch, is to be congratulated on the success of the policy of replacing isolated papers by discussions on topics of wider interest.

H. T. H. P.

Biological Standards*

THE proceedings of the meeting of the Permanent Commission on Biological Standardization held at Geneva in the autumn of 1935 have been published, together with the reports of the technical experts to whom a number of different questions dealing with biological standards had been referred.

Six standards were adopted or redefined by the Commission. The pituitary (posterior lobe) powder and the *Digitalis purpurea* leaf powder, at present in use as standards in Great Britain, stocks of which are held at the National Institute for Medical Research, Hampstead, were adopted as international standards, and the Institute was asked to distribute them on behalf of the Health Organisation. The original international standard pituitary powder was prepared by Prof. Voegtlin and was available for issue to authorities desirous of testing their national standards, but up to that time no laboratory had been entrusted by the Commission with its general distribution: the two preparations are of the same activity. The original international digitalis standard powder is nearly exhausted; but the stock of the British Standard is sufficient for international requirements for some time: its potency is, however, greater than that of the previous standard, so that one unit is represented by 0.08 gm. of the new standard, as compared with 0.1 gm. of the previous preparation. A crystalline sample of insulin was adopted as standard and defined as containing 22 units per mgm. The previous standard was amorphous

and contained 8 units in one milligram. Two standards for substances for which standards had not been previously available were recommended for adoption: one for *B. histolyticus* antitoxin, and the other for diphtheria antitoxin for use in the flocculation test. The question of the standards for asphenamine and its derivatives was left for further consideration by a small technical committee.

It was further agreed that work should be carried out on tetanus antitoxin, poliomyelitis convalescent serum, staphylococcus antitoxin and antityphoid serum. The recommendations adopted by the inter-governmental conference on biological standardization were considered and certain subjects recommended for further examination, including the standardization of anti-anthrax serum, anti-swine erysipelas serum, anti-venom serum and the preparation of a standard *Digitalis lanata* leaf powder.

The bulk of the report is devoted to the reports of the experts who have been examining proposed new standards, and gives the evidence on which the Commission has based certain of its recommendations: for the details of these experiments the original report must be consulted. The separate sections deal with insulin, histolyticus antitoxin, diphtheria antitoxin, tetanus antitoxin and antipoliomyelitis convalescent serum. The bulletin also includes reports of the Standards Departments of the National Institute for Medical Research, Hampstead, and the Statens Serum Institute, Copenhagen, and concludes with a useful description of a simple laboratory method for the desiccation of serum and other protein solutions.

* Quarterly Bulletin of the Health Organisation. Special Number, November: Biological Standardization (2). (Geneva: League of Nations; London: George Allen and Unwin, Ltd., 1936.) Pp. 571-745

University Events

GLASGOW.—Prof. George Barger, professor of chemistry in relation to medicine in the University of Edinburgh, has been appointed Regius professor of chemistry in the University in succession to Prof. George Henderson, who has resigned.

Dr. Noah Morris, lecturer in biochemistry, has been appointed professor of materia medica and therapeutics.

Science News a Century Ago

The Iron Ship *Sirius*

THE first iron ship to be classed by Lloyd's Register of Shipping was the steamer *Sirius*, the records of Lloyd's Register stating she was built under the inspection of the Society's London surveyors, and intended for service on the River Rhone, her port of registry being Marseilles. The *Sirius* was built by William (afterwards Sir William) Fairbairn at his yard at Millwall, which afterwards formed a part of the yard at which the *Great Eastern* was constructed. According to the *Railway Magazine*, she was launched on September 26, 1837, and she was the longest vessel so far built of iron. She measured about 164 ft. in the keel and 176 ft. on deck. Her beam was 17 feet. She was intended to be worked by two high-pressure engines of 35 horse-power each having a 24-in. cylinder with a stroke of $3\frac{1}{2}$ ft. She was to have three boilers with copper tubes. "The iron planks of which she is made", said the *Railway Magazine*, "are about 7 ft. long, 14 in. wide and a quarter of an inch thick, and her ribs are of double angle iron with diagonal stays. Her mould is handsome, but rather narrow; and when she has her machinery and water, it is calculated she will not draw above two feet of water. She is besides, divided into four compartments by three iron water-tight bulkheads; so that if a fracture should happen in any one part she will still float safely."

Fossil Discoveries in France

IN its column of Miscellanea, the *Athenaeum* of September 30, 1837, under the title "More Fossils", said: "M. Axéna has found some fossil bones of mastodons and the rhinoceros, reptiles, and some well-preserved fruits in the parish of Sauveterre, near the district explored by M. Lartet, whose discoveries we announced some time back. We should like to ascertain whether the skeleton of the new and remarkable rhinoceros brought from behind the Cape by the expedition under Dr. Andrew Smith, presents more affinity to the recent or to the fossil species. It seems that the new fact concerning fossil quadrumana has been succeeded by a similar discovery in the Himalaya mountains, but which is not so curious as the circumstance of finding these animals in Europe; and what is still more extraordinary, the comparative anatomists have determined the European species to be similar to those Gibbons which inhabit the remotest parts of Asia. M. Lartet's discoveries have given rise to much discussion in the French Academy of Sciences. . . ."

Reforms in the Hospitals

A CORRESPONDENT signing himself "Spectator" in a letter to the *Lancet* of September 30, 1837, mentions the following improvements which had taken place

at the London hospitals during the previous ten years:

"1. The introduction of clinical lectures, a department of instruction which was before shamefully neglected in this country, and is even yet but imperfectly taught. 2. The publishing of hospital reports, a measure forced upon the medical officers by *The Lancet*. 3. The annual distribution of prizes to the students (which did not become general until after 1826). 4. The withholding of certificates unless a few lectures have been attended; for I remember the time when it was not an uncommon occurrence for a student to boast that he had received a certificate without having attended a single lecture. Lastly, I may mention the posting of post-mortem examinations; the absence of hole and corner operations; the establishment of clerical clerkships, the greater punctuality in the visits of the medical officers (although, I confess, there is much yet to reform in this respect) and the frequency of periodical examinations by some of the teachers may also be added to the list of benefits on the part of the students which have reluctantly been obtained from the 'Dubs and Pures'."

Medal Striking

THE *Gentleman's Magazine* of September 1837 contains the following announcement: "M. Pistrucci, chief medallist in the Royal Mint, has discovered a method by which he can stamp a matrix or a punch from a die which has never been touched by an engraver, and yet still make the medal identically the same with the original model in wax; an operation by which the beauty and perfection of the master's design are at once transferred to any metal, whether gold, silver or copper, by striking it according to the usual process. The model being made in any substance, wax, clay or wood or other fit material, a mould of it is taken in plaster, from which mould when dried and oiled to harden it, an impression is taken in sand, or other similar substance which may be preferred, and from this again a cast is obtained in iron as thin as possible, that the work may come out sharply, and the iron attain the hardness almost of a steel die hardened."

Spirit Drinking in India

AN editorial in the *Indian Journal of Medical and Physical Science* of October 1, 1837, contains the following warning to the Government: "The lives of European soldiers in this country are unhappily passed in a state of imprisonment in their barracks from 10 o'clock in the morning to 4 o'clock in the evening. There is nothing of that change of scene and agreeable occupation of time as experienced by British soldiers in their own congenial and delightful country. Their indolence and want of amusement tend to a despondency of mind, and to depression of the whole animal functions, to arouse which spirits are had recourse to, and which is in fact looked upon as a necessary and luxurious pastime, sanctioned as a ration, and approved of as a custom. Canteens are rooms appointed by military rule as a place of refuge to gratify the appetite, by adding the indulgence in liquor to social conviviality. But is the Government of the country aware that all this breaks up the physical energies both bodily and mental of their brave troops?"

Societies and Academies

Paris

Academy of Sciences, July 19 (*C.R.*, 205, 185-264).

MARCEL DELMONT and CHARLES HANEGRAAFF: The catalytic hydrogenation of cinnamic aldehyde and of citronellal. Study of the order of attack of the aldehyde group and the double bond, using Raney nickel with and without platinizing.

RICHARD FOSSE and ROGER DE LARANCHEGUE: The mechanism of the synthesis of cyanamide in the oxidation of glucose in the presence of ammonia.

HENRI COLIN and HENRI BELVAL: Chemical affinities and classification in the *Hordeae*.

PIERRE LEJAY: New determinations of the acceleration of gravity in Europe and in the Levant.

JACQUES DE LAPPARENT: Ancient phenomena of rubefaction in the central Sahara.

LUCIEN DANIEL: New observations on grafting.

FOLKE ODQVIST: Equations of compatibility for any system of orthogonal triple co-ordinates.

LUCIEN GODHAUX: Algebraic varieties of genus unity containing cyclic involutions.

M. EIDELHEIT: Systems of linear equations with an infinity of unknowns.

J. KUNTZMANN: Homomorphy between multiform systems.

ROBERT WAGNER: Multivalent functions in space of matrices.

FLOREN VASILESCU: An application of normal families of distributions of mass.

NICOLAS CIORANESCU: The deformation of elastic plates in the case of analytical data.

JEAN GALIBOURG and PIERRE LAURENT: Sub-permanent deformations (reactivity phenomena).

JEAN MALFITANO: The constitution of the photon considered as a dipole.

MME. ZINA SOUBARNW-CHÂTHLAIN: The variations of conductivity undergone by dilute solutions of molybdic acid in the course of their neutralization. The experiments described support the theory of the existence of the acid H_2MoO_7 .

O. DONY-HÉNAULT and A. DE JAMB: Study of electrolytic vessels with mercury cathode.

MAURICE FALLOT: The magnetic properties of the alloys of iron with ruthenium and osmium.

ROGER SERVANT: The double refraction of quartz in the extreme ultra-violet and the Schumann region.

LUCIEN MAILLET: The emission of X-rays by vacuum tubes of very small dimensions, submitted to a high-frequency current. The tubes described were 2-6 cm. long and 3-5 mm. in diameter, fitted with a single wire anode. Some applications in the field of radiotherapeutics are indicated.

MORDECHAI BOBTILSKY and MILM. MELANIE RAPPOPORT: The decomposition of hydrogen peroxide in the presence of a cobaltictric complex compound as catalyst.

PIERRE TEUNEL: The electric moments of some fatty dinitriles.

RAYMOND QUELLET and JEAN ALLARD: The chloromethylation of anisic aldehyde. Passage to 1-methoxy-2-methylol-4-methylalbenzene.

LUCIEN DAUTERIBANDE, PIERRE ANGENOT and EDMOND DUMOULIN: Study of antiserol esparto grass filters. The influence of the hygrometric state on the penetration of antiserol filters. The influence of the time of passage of the moist atmosphere.

R. RUSSO: The Kimmeridgian age of the terminal layers of the western Beni Snassen (Morocco).

CHARLES CHABROLIN: The germination of the seeds of *Orobancha speciosa*.

ROBERT ECHVIN and ROGER ULRICH: The nature of the intravacuolar inclusions in the fruit of the ivy (*Hedera Helix*).

PIERRE DRACH: Generalities on the development of the crystalline textures in the tegumentary skeleton of the brachyurous Decapods.

JEAN RÉGNIER and ANDRÉ QUINVAUVILLER: The influence of the nature of the acid on the action exercised on the motor nerve by different salts of novocaine and morphine: different qualitative behaviour according to the concentrations.

PAUL FORTIN: Very clear entoptic vision of the retina in the orange red.

MARCEL AVEL: Experimental analysis of the determination of the dorso-ventral axis in the regeneration of the head in worms.

ETIENNE WOLFF: Egg laying anomaly in an intersexed fowl, after the action of androsterone, on the Müller ducts of the embryo.

AUGUSTIN BOUTARIO and MME. MADELEINE ROY: Spectrophotometric researches on aqueous solutions of bile.

JEAN LOISELUR and MILM. RENÉE COLLIARD: The adsorption of polypeptides by the proteins of the blood serum.

CHARLES CHAMFY, MAURICE HEITZ-BOYER and ROGER COUJARD: The mechanism of the hormonal sexual actions on the dysuria of prostatitis.

Moscow

Academy of Sciences (*C.R.*, 15, No. 5, 1937).

S. BERGMANN: A theory of functions satisfying a linear partial differential equation (1).

V. S. IGNATOVSKI: The Laplace transformation (8).

L. LUSTERNIK: A generalization of the equation of the Sturm-Liouville type.

A. BOBROV: The relative stability of sums of positive quantities.

V. FOCK: The Bose amplitudes in the neutrino theory of light.

A. TOPORSO: The mechanism of the formation of atomic and colloidal centres of silver in alkali phosphorus halide.

L. I. BELAJEV: The problem of the electrophoresis of lamellae at the interface of liquid phases.

P. J. SCHMIDT and G. P. PLATONOV: Anabiosis and fish transport without water. Experiments are described showing the possibility of preserving chilled fishes alive for more than twenty-four hours, while smaller fishes can be revived after chilling for ten days.

J. N. GOLUBINSKI: A tetraploid form of *Ocimum corymbosum* Sinis produced experimentally.

D. J. VAKULIN: Reaction of reversibility in *Perilla ocymoides* L. under natural conditions.

T. T. DEMIDENKO: Iron in the nutrition of higher plants.

V. L. VAGIN: The position of the Ascothoracida ord. nov. (Cirripedia Ascothoracica Gruvel 1905) in the system of Entomostraca.

P. J. SCHMIDT: The Pacific genera *Eurymon* Gilbert and Burke and *Gilbertidia* C. Berg (Pisces, Cottidae).

G. V. LOPASHOV: (i) The formation of organs in organisms deprived of the nervous system. (ii) The specificity of inductive influences.

Forthcoming Events

[Meetings marked with an asterisk are open to the public.]

Wednesday, September 29

SOCIETY FOR THE STUDY OF ALCHEMY AND EARLY CHEMISTRY, at 8—(at University College, Gower Street, W.C.1).—Dr. D. McKie: "Some Early Work on Combustion, Respiration and Calcination".*

NATIONAL SMOKE ABATEMENT SOCIETY, October 1-2.—Ninth Annual Conference to be held at Leeds. Dr. H. A. Des Voeux: President.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

CIVIL ENGINEERING ASSISTANTS in the Headquarters and Divisional Road Engineer's Offices of the Road Department of the Ministry of Transport—Establishment Officer of the Ministry, Metropolis Buildings, Northumberland Avenue, W.C.2 (September 27).

ASSISTANT IN THE DEPARTMENT OF CIVIL ENGINEERING, Queen's University, Belfast—Prof. Hummel (September 28).

ENGINEER in the Directorate of Factories, War Department—Chief Superintendent, Ordnance Factories, Royal Arsenal, Woolwich (September 28).

ASSISTANT MASTER FOR MECHANICAL ENGINEERING in the Llanelli Mining and Technical Institute—Clerk of the Education Committee, County Education Office, 24 King Street, Carmarthen (September 28).

A DESIGNER (Ref. No. 543 B) and AN ASSISTANT (Grade II) (Ref. No. 540 B) for work in the Stress Section of the drawing office, and a TECHNICAL OFFICER (Ref. No. 574 B) and ASSISTANTS (Grade III) (Ref. No. 589/590 B) for work on electrical equipment of aircraft, at the Royal Aircraft Establishment, South Farnborough, Hants—Chief Superintendent (October 1).

ASSISTANT LECTURER in the CHEMISTRY DEPARTMENT at Robert Gordon's Technical College, Aberdeen—Secretary and Registrar (October 2).

JUNIOR ASSISTANT in the Science Museum Library—Director (October 4).

LECTURER in PHYSICS in the South-East Essex Technical College, Dagenham—Clerk to the Governors (October 4).

OFFICER-IN-CHARGE OF POULTRY RESEARCH SECTION, Imperial Veterinary Research Institute, Izanagar, United Provinces, India—High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (October 8).

CHIEF LECTURER in MECHANICAL ENGINEERING at the West Ham Municipal College, Stratford, E.15—Principal (October 9).

TWO ASSISTANT KEEPERs (Second Class) on the Higher Technical Staff of the Science Museum—Director, envelopes marked "Assistant Keeper" (October 11).

SECOND ASSISTANT PETROLEUM TECHNOLOGIST for the Government of Trinidad and Tobago—Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, London, S.W.1 (October 15).

WM. HUDSON PROFESSOR OF ECONOMICS in Natal University College, Pietermaritzburg and Durban, South Africa—Registrar, Natal University College, Pietermaritzburg, Natal (November 9).

ASSISTANT in Zoology in the University of Glasgow—Secretary, University Court.

MASTER FOR MECHANICAL ENGINEERING at the Technical Institute, Ashford—Principal.

RAILWAY ENGINEER (temporary) for H.M. Office of Works—Chief Architect, Room 66A/3rd, H.M. Office of Works, Storey's Gate, S.W.1.

Scientific Aspects of Industrial Accidents

THE annual report of the Chief Inspector of Factories and Workshops for the year 1936 (Cmd. 5514. H.M. Stationery Office, 1937. 2s. net), raises several questions with which scientific workers are concerned, whether actually engaged in industries or as citizens interested in the protection of national health from conditions which would degrade it. Anyone reading the report would be disturbed at what is revealed in it as to the very long hours that are being worked in some of the newer industries. While in the nineteenth century, broadly speaking, Great Britain undoubtedly led the world in imposing limitations on hours of work and the observance of minimum standards of safety and health in factories and workshops, in the last few decades it is clear that the country has fallen sadly behind other important industrial countries in these matters.

The report shows that although the 47 or 48 hour week is considered normal, many cases are reported where the working week exceeds 48 hours, not only for busy periods but often also continuing for months at a time or even for most of the year. Work up to 50 and even 60 hours a week has been common in laundries, the metal trades in the Midlands, as well as in leather, bakelite and other industries and in the woollen and worsted trades, and some disconcerting examples of illegal employment of women and juveniles are cited in the report. Despite the improvement in the employment situation, unemployment is still far too severe and widespread for this situation to be regarded with equanimity. Obviously the inspectorate requires very much stronger and clearly expressed support from public opinion if even the minimum standards required by the law are to be enforced

and these abuses suppressed, nor can we feel confident that the advance represented by the provisions of the new Factories Act now passed will effect any improvement unless there is a very considerable increase in the inspectorate.

A significant share of that support may well be looked for from scientific workers, whether engaged in industrial work or not. Apart altogether from the posts of responsibility in the management of industry which many of them hold, they should not require this report to realize the connexion between long hours of work and industrial accidents and sickness, which is once again so clearly portrayed in its pages. On this subject parts of the report are painful reading. A substantial increase in accidents over the previous year is again recorded—about 15 per cent for accidents generally and 9 per cent for fatalities. Although the analysis and graphs submitted by the chief inspector afford some evidence that the risk of accident is tending to decrease, through such factors as the work of the inspectorate, the educational work of the National Safety Association, the Industrial Welfare Society and similar organizations, the closer supervision of the growing number of factory safety organizations, and especially through the growing recognition of their responsibility in this matter by employers, disturbing fluctuations in the risk of accident as well as in the numbers of accidents still occur from year to year.

Some of the causes of these fluctuations are obvious. The longer hours to which reference has already been made are a significant factor. The greater speed of production, the absorption of more inexperienced or unpractised workers, both old and young, and the installation of new plant

and machinery with unknown risks, are among other factors which are responsible for the rising toll of death and injury, and appear at present to be associated with increased production and prosperity.

That this position should be accepted as inevitable may well be challenged. Already there are many firms, both large and small, in which the safety of the worker is a first consideration, and where no new machinery or process is put into operation without every possible measure being taken to ensure that it is as safe as it is eventually intended to be. It should not be too difficult a task for professional associations and safety organizations to arouse public opinion in such matters to a point which would ensure not merely that the minimum requirements of the law were rigorously enforced, with adequate penalties if need be, but also that a high incidence of avoidable accidents, especially among the young workers, would be regarded as a definite slur on the reputation both of the firm and of its management.

The position of the juvenile worker requires special stress because of the exceptionally high accident rates among workers under eighteen years of age to which the report again directs attention, and also because of the possibilities of a much more rapid reduction in this accident rate among juvenile workers than among adults in the same occupation. While accidents to young workers are usually of the less serious kinds, the situation was regarded as sufficiently important to receive special attention from the inspectorate, and a separate chapter of the present report deals with accidents to young workers and methods of preventing them. In relation to young workers the question of industrial safety presents its own problems, and too often it appears beyond doubt that the special protection which should be accorded to young workers is wanting.

An attempt to apportion responsibility between the employer and the victim indicates that in only 23.8 per cent of the accidents to boys could no blame be attached. In 32.3 per cent of the accidents the firm was mainly responsible and in 44.3 per cent the boy. The figures for girls do not differ greatly, but in 51.1 per cent of the accidents the girl was mainly responsible. The inquiry also emphasized the greater liability to accident in the initial stages of employment; about 10.4 per cent of the boys and 24.4 per cent of the girls who were injured in the first six months being injured during the first week.

These figures alone emphasize the significant part which a sense of responsibility on the part of the management, combined with active oversight, can play in determining the standard of safety in a works, and they stress, too, the importance of educating the young worker in the risks attached to his work as well as the importance of selecting that work, and adequate supervision and training in the initial period of employment. In spite, however, of the attention directed to this matter as a result of a memorandum issued following a conference convened by the Home Office, in which the National Confederation of Employers' Organizations participated, the general progress has been unsatisfactory. The publicity given to the matter has as yet aroused little, if any, interest in many employers, and others have had no knowledge of it.

A large proportion of the accidents to juveniles appear to occur in the smaller factories, where only individual approach is likely to be effective, and the chief difficulty lies here rather than in the larger and better organized factories. Whether the factory is large or small, however, the interest of the occupier, managers and foremen is indispensable before there can be much hope of a noticeable reduction in these accidents.

For this reason, the interest and co-operation of the scientific worker in this matter is of prime importance. Whether or no he occupies a position on the management side, an experienced chemist or engineer, for example, is usually able to initiate steps leading to improved working conditions and to secure the formulation and observance of strict safety rules. He has also an indispensable contribution to make on the technical side in improved design or safer operating methods and conditions in new or established processes. His personal interest may largely determine the success or failure of attempts at educating the young recruit or in securing that the training and supervision he receives is efficient and not perfunctory.

Nor is this the only contribution which scientific workers can make in the field of industrial safety and accident prevention. Besides the enthusiastic and skilled leadership and co-operation of the man of science, whether in a technical or an administrative capacity, there is needed an alert and informed public opinion which will not tolerate the continuance of the abuses revealed in this report. Ridiculously inadequate penalties are at present inflicted for such exploitations of health and safety as the employment of boys of fourteen to

seventeen years of age for as many as eighty hours a week, of girls of fourteen from fourteen to fifteen hours a day, and women for an unbroken twenty days work, which are in themselves an obvious cause of industrial ill-health and accidents. Clearly the strong pressure of public opinion is urgently needed to stir some magistrates to a sense of responsibility in this matter, and a Government which professes so great an enthusiasm for physical health and training might do well to convey a strong hint to the offending quarters to discourage lenity as ill-timed as it is reprehensible.

This problem of arousing a public opinion will secure the observance not so much of the minimum standards of the law but rather of the practice of the more progressive firms, whether large or small, and supply the support which such firms, no less than the factory inspectors, themselves require, is less a matter for an individual scientific worker than for his professional associations. They indeed can afford the individual worker the

moral support he may need in making his stand against specific negligence or abuses which he may encounter in his ordinary industrial life, as well as supplying the stimulus and vision which may induce him to initiate constructive measures whether in the technical or more general sphere. Equally they could, if they chose to speak with a united voice and authority, mould public opinion and bring to an end the neglect and indifference which are as detrimental to industrial efficiency as to the health and well-being of the whole nation, and not only that of the individual workers, young and old, of whose lives and happiness so distressing a toll is now taken. The present report may well stir such professional associations as the British Association of Chemists and the Institute of Chemistry to take a more active part in creating an informed public opinion and in strengthening the hands of their members, especially when employed in professional isolation in the small firms where improvement is most needed.

National Factors of Physical Fitness

National Fitness:

The First Steps. (Issued by the National Advisory Council and the Grants Committee for Physical Training and Recreation.) Pp. 24. (London: H.M. Stationery Office, 1937.) 2d. net.

Physical Education in Germany

(Board of Education: Educational Pamphlets, No. 109.) Pp. 80. (London: H.M. Stationery Office, 1937.) 1s. net.

ON Tuesday, July 20, a striking leader appeared in *The Times*, entitled "The Empty Chair". It referred to the fact that physical culture had no conspicuous place among the subjects to be discussed at the annual meeting of the British Medical Association at Belfast. "If the doctors will not fill the empty chair, others less well qualified than they will fill it". "Into this pageant of life in action the science of nourishment and the science of personal hygiene will fit easily and with propriety. . . . This is the larger physiology. . . ." The complaint is just and timely. Physical training is largely neglected by doctors and physiologists in Great Britain, and it is almost impossible to obtain expert scientific advice on it.

The Physical Training and Recreation Act passed through Parliament this year. The little

pamphlet "National Fitness" shows how the National Advisory Council and the Grants Committee are beginning to plan the organization by which the Act may achieve its ends. It is curious that Great Britain—the home of 'sport'—is so backward in matters relating to the physical education (in its widest sense) of the people. How many of its towns have running tracks, gymnasia, swimming baths? How many of its schools and universities have means and personnel for the physical examination and assessment of their students? How many of our young people, lacking advice and encouragement, know anything of the joys of bicycling, tramping, camping (and singing) about the countryside? How many more than at present, even without help and leadership, might find out for themselves, in their holidays and week-ends, were the Youth Hostels multiplied ten times in number and capacity? How much health, happiness and content might result were there reasonable means of physical recreation, with organization, leadership and advice, within the reach of all instead of a small fraction of our people?

The beginning of a national effort is being made. Its success will depend on various factors: first, on public opinion, which, as the pamphlet truly says, "in this country means the opinion of the

people". It will be a sad thing for democracy if "the opinion of the people" in this matter of health and happiness continues to lag behind the accepted teaching of dictatorship. Secondly, on the provision of teachers and leaders: here again democracy has proved lamentably slow, but the pamphlet promises that "a new National College is being established". Will people of sufficient character, intelligence and enthusiasm come to be trained? And will there be assured careers for those who come? Thirdly, on the provision of financial and material means: the funds available to the Grants Committee are not small, but will they be sufficient? This is, or ought to be, a big business. Fourthly, on expert scientific advice on the physiological, medical, nutritional and psychological aspects of a many-sided problem. Such expert advice implies, not mainly consultation in committee (though that is necessary), but chiefly the handling of human beings: it requires, on one hand, something analogous to the clinical experience, the aptitude and sympathy of the good physician, on the other a trained capacity for making correct assessments and drawing accurate conclusions from human data. The "empty chair" will remain empty, or will be filled—as *The Times* said—by someone less well qualified, unless physiologists, medical men, experts in nutrition and psychology, realize that the production of health and fitness is at least as important as the treatment of disease.

The other pamphlet is the "report of a delegation who visited Germany in November last to investigate Physical Training there". It will be deplorable if a great and generous achievement, from which Great Britain might learn much, is disregarded or depreciated because of the indignation which many of the manifestations of national socialism have rightly evoked here, or because of some of the exaggerations and excesses of the achievement itself. The Hitler-Youth, with its six million (most of them) eager youngsters, is admittedly political: that, as the report points out, is no doubt unfortunately—the German habit in physical education: and it has many aspects which, from the British point of view, are odd or objectionable. It takes children unduly from their homes; it sometimes injures them by over-exertion; although nominally voluntary "he is a rash lad who ventures to say that he proposes to stay out of it". It encourages its children to read some queer literature. Its potential military value, also, may be enormous; but so indeed is that of any group, sufficiently large, of happy, healthy people, disciplined in outdoor sports and activities, inured to hardship, bound by common loyalties. The fact that healthy loyal youngsters may make better and more ready soldiers is no

reason why unhealthy, cramped and discontented ones should make a better population.

The truth is, whether we like it or not, and as a comparison of these pamphlets shows, that, in its encouragement to youth (and middle age) to find happiness and recreation in the open air, and to develop health, skill, stamina, strength and self-respect by games and bodily exertion, Germany has gone very far beyond Great Britain. In some respects it has gone too far, but that may be repaired as experience is gained. The achievement is not due only to enthusiasm and devotion. In the "Napoli" schools "the doctor is a most important member of the staff". Research in physical education "is beginning to be of interest to the biologists in the universities". The National Physical Training Academy offers "facilities which are far beyond those which any institution in this country can provide". The training of teachers in physical education, and of leaders in sport, gymnastics and outdoor recreations (teachers and leaders of either sex), is rigorous and scientific: and some of the best and most eager of the young people are enrolled. Architecture, music and psychology are called in: "the spaciousness, simplicity and very often the beauty of the surroundings of establishments in Germany were most noticeable". Singing is widely encouraged and "is invariably excellent". "Kraft durch Freude" (strength through joy) may have a slightly comic ring in English ears, but its appeal to the German masses is based on sound psychology and on skilful, arresting propaganda. This organization affects the lives of millions of young (and older) workers: it is generous and reasonable in spirit: it provides, apart from anything else, cheap, ready and beneficial holidays for the masses: it is "possibly the most instructive phenomenon of the Third Reich". If its cost is great, so also will be its result in health and happiness to the German people.

A free democracy such as ours is liable to be slow in its enthusiasms and to be inhibited by criticism, and it may be a long time before we learn to do for our young people what Germany is already doing for hers. A comparison of these pamphlets shows how far, in eagerness, in organization and in science we are behind. Our best, in physical education, is doubtless at least as good as the German best, but Germany is doing well for far more people. Britain may have little else to learn from national socialism, except by way of warning, but we shall be fools—or worse—if we allow prejudice to blind us to a real achievement in human betterment, if we refuse to acknowledge the one generous experiment which, whatever its motives, exaggerations and shortcomings, Nazi Germany is now making.

A. V. HILL.

Enzyme Research

Ergebnisse der Enzymforschung

Herausgegeben von F. F. Nord and R. Weidenhagen. Band 6. Pp. x + 289. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1937.) 23.60 gold marks.

THIS year's volume of the "Ergebnisse" deals in the main with the remote sections of the subject and to that extent is of special rather than general interest. Inasmuch as progress on the experimental side depends on the development of new technique, some of the contributions are of importance. For example, two Indian investigators in Bangalore deal with the application of dilatometry to enzyme reactions, which involves the measurement of volume changes under carefully standardized conditions. Though the mechanism through which volume change is caused is not clearly understood, it is claimed that the validity of its application has been established in specific cases by a comparative and critical study. The practical difficulty is to be sure that the reaction, or rather mean result of possibly several reactions measured, is the one which the experimenter describes.

Perhaps the most interesting chapter is that by Hugo Theorell of Stockholm on the yellow ferment and its component, known in crystalline form as lactoflavin, which appears to be vitamin B₂ and about which so much has been discovered working with extremely small quantities of material. In the ferment, the presence of which must be regarded as essential to life, the lactoflavin is joined to a pentose sugar, phosphoric acid and protein, a combination which seems usual in the cell. It acts as a hydrogen carrier, the physiological problem being whence comes this hydrogen and whither it goes. Lactoflavin has been synthesized. The summary is a useful one of this most important subject.

Miss Stephenson, of Cambridge, writes of hydrogenylase—an alarming word to describe bacterial enzymes which produce molecular hydrogen from formic acid. The work done on this reaction indicates that since all substances so far known to yield hydrogen by bacterial action also yield formic acid, the hydrogen is liberated from this substance.

A somewhat lengthy paper contributed from Lwów, by J. K. Parnas, deals with the vexed question of the changes which take place during the breakdown of glycogen in muscle. The changes are complex, and they involve phosphates; there

is much controversial matter in the article, which would have been improved by a summary. The editors of the "Ergebnisse" should encourage authors, even in the most specialized fields, to make clear wherever possible the probable position in relatively simple language and not leave it to the unfortunate general reader to become lost in the confusion of contradiction and detail.

Everyone must experiment with heavy water in these days, and there is a section on ferment reactions in its presence from K. F. Bonhöffer of Leipzig. It is largely mathematical and does not make any particular point.

The chapter by Emil Abderhalden on the protective ferments demands careful study. Apparently when foreign substances of a hydrolysable character are introduced into the blood stream, it is not long before appropriate new enzymes appear capable of breaking them down, and these enzymes afterwards appear in the urine. These protective proteinases are characterized by being sharply specific towards the substrate which has called them into being. Their origin has not been discovered; they can be detected in blood serum and in urine within less than 24 hours of the introduction of the foreign substance. The subject is a new one and obviously of outstanding importance. It is interesting to note the two conflicting trends in enzyme theory—some emphasize the absolute character of the specificity, others consider a particular enzyme, for example emulsin, to have a wide range of activity though it acts on some substrates with extreme slowness.

Lastly may be mentioned an American contribution, by J. B. Summer of Ithaca, on antiurease, a member of the class of anti-enzymes of which sixteen have already been mentioned in the literature. Crystalline urease being available, it was possible to study the production of antiurease by injecting it into an animal. The author speaks of having made the purest antibody preparation yet obtained, though he has not yet succeeded in crystallizing it. This work is of importance.

These brief extracts must suffice to show some of the directions in which hopeful progress is being made. The work is truly international, the laboratories of the world are co-operating in it and it is worth while to stress this, the real and the predominant aspect of scientific chemical activity, as the true state of affairs, and to regard the excessive reference to warlike activities as largely an overstatement.

The Rengma Nagas: A Changing Tribe

The Rengma Nagas:

By J. P. Mills. (Published by direction of the Government of Assam.) Pp. x + 381 + 17 plates. (London: Macmillan and Co., Ltd., 1937.) 25s. net.

MORE than fifteen years ago, the reviewer in *NATURE* of an earlier monograph in this series expressed the hope that it might be followed up by monographs on other Naga tribes including the Rengma, and Mr. J. P. Mills, honorary director of ethnography for Assam, in dealing with that tribe, has now filled in one gap in our existing knowledge, so that we have a series of works dealing with all the tribes occupying the middle of the major portion of the administered area of the Naga Hills.

The gaps in our knowledge have been filled in more ways than one, for while Mr. Mills has found less to say about the social organization, for example, of the Rengma, than he had to say about the Ao in his last monograph, he has given even greater details of minor observances, formulæ and superstitions of daily life. Thus we are told exactly what a man should do when he is going out to snare hornbills, or precisely what misfortunes befall a man who remarks how good a wild yam tastes.

The author is, by the way, perhaps too sweeping in describing the Great Indian hornbill as feeding "exclusively on fruits and berries"; at any rate, a tame one, which belonged to the reviewer and lived unopinioned in his garden, spent much time in searching for spiders in the thatch, and preferred butter even to mulberries. Incidentally, also, the Angami dye referred to in a footnote on p. 66 is made from the leaves not, strictly speaking, of an oak tree, but of the *Macaranga denticulata*, and, in order to obtain the true black, a cloth must first be boiled with macaranga leaves and then steeped in black mud, the iron salts in which act on the gallic acid from the tree to make a fast black.

Particularly interesting are the details which Mr. Mills gives of a purificatory ceremony of a kind not previously described, the reviewer believes, in any monograph of this series.

The Rengma are a tribe now split into three groups; one of these migrated westwards to the Mikir Hills in the first quarter of the nineteenth century; the other two remained in the Naga Hills, but have become widely separated by the northward migration of the Sema tribe. It is with the last two sections that Mr. Mills's monograph deals, and he speaks of them throughout with reference to the Naga Hills administrative district as the

Western and the Eastern Rengma, but the Middle, or Central, and Eastern would be more precise terms. It is unfortunate that official duties made it impossible for him to deal with all three groups, since the changes which have taken place in the westernmost group, everywhere in contact with other peoples, have been very great, and would have afforded an interesting, if depressing, example of the effects of cultural contact and subsequent sophistication.

Even so, Mr. Mills has some very important reflections to make on certain aspects of missionary teaching, particularly as to the policy sometimes pursued of discouraging the payment of marriage prices. The tendency of the mission has been, if not actually to discourage, at best to refrain from encouraging the practice of paying a substantial sum for the privilege of marrying a man's daughter. The practice is a healthy one, as it provides some economic insurance for proper treatment of the bride by her husband, who stands to lose the sum paid if his wife leave him under provocation, and for the good behaviour and fidelity of the wife, who in turn must refund the payment if she give good ground for divorce. In some Sema villages where the custom had been dropped on conversion to Christianity, a tendency was manifested towards a quite uncalled-for and unjustifiable putting away of wives, or desertion of husbands, since the unfaithful party stood to lose nothing by the change.

Mr. Mills defends the payment of marriage prices among the Rengma on similar grounds, and it might be added that the retention of the custom is particularly desirable in the interests of the bride where there has been a recent change from polygyny to Christian monogamy, and where the tendency towards marrying more than one wife is likely to show itself in divorce and re-marriage if there be no serious obstacle.

The Government of Assam is the one administration in the Indian Empire that has the wisdom, the foresight and the interest in good governance to produce a series of detailed accounts of the customs and lives of the peoples of primitive culture surviving in the wilder parts of its province. This one is more than worthy of its precursors; it is well produced, well illustrated and well indexed. Two misprints only (on pp. 69 and 92) were detected by the reviewer, but he badly missed a map. Both Mr. Mills and the Assam Government are to be congratulated on this addition to their unrivalled series of tribal monographs.

Mitogenetic Radiation and the Theory of Nerve Excitation

Mitogenetic Analysis of the Excitation of the Nervous System

By Prof. A. G. Gurwitsch. Pp. ii+114. (Amsterdam: N. V. Noord-Hollandsche Uitgeversmaatschappij, 1937.) 3.75 f.

THE outcome of Prof. A. G. Gurwitsch's latest monograph is a new 'chain reaction' theory of excitation, based, in its more concrete form, on the experimental results described in the body of the book. The peculiarity of the new theory is that it allows for the existence of many qualitatively different states of excitation, while ignoring completely the electrical, thermal and chemical phenomena studied by classical methods. The more general considerations which appear in the concluding chapter will perhaps receive better attention, and will doubtless awaken the sympathy of those who, with Gurwitsch, feel that the study of electrical changes in artificially stimulated nerve affords an inadequate basis for the comprehension of the "unlimited variability . . . and the continuity of functional states" of the nervous system. These ideas are derived from Driesch and from Gurwitsch's earlier work on the "cerebral field", and owe little to his study of mitogenetic radiation.

The experimental foundation of the new theory is somewhat as follows: Resting medullated nerve, in common with many other biological systems, is said to emit a complex ultra-violet spectrum of exceedingly low intensity, which originates in the nerve fibre itself. The medullary sheath, although highly opaque to ultra-violet radiation of macroscopic intensity, contrives to transmit the radiation emitted from the nerve fibre by a remarkable chain process of absorption and secondary emission, so that it can conveniently be observed externally by its effect on the rate of division of yeast cells—an aspect of the subject that has already been subjected to destructive criticism (see *Biol. Rev.*, 10, 42 (1935); and *NATURE*, 133, 860 (June 9, 1934)). "Biological" spectral analysis of the radiation, and comparison with that produced by enzyme reactions proceeding *in vitro*, suggest that it can be used as an index of the chemical processes occurring in nerve. It is found that whereas the resting sciatic emits radiation due to glycolysis, oxidation and proteolysis, the stimulated nerve gives a different radiation, the composition of which depends on the mode of excitation—mechanical, electrical, reflex, etc. Thus, in Gurwitsch's opinion, the existence of a qualitative variability of states of excitation is established. Sub-threshold stimuli, moreover, also give rise to a propagated

disturbance, accompanied by characteristic chemical changes, so that the all-or-none law appears to be a mere artefact, ascribable to the too exclusive interest of classical physiologists in action currents, excitability, and so forth.

Not only does nerve show this variability of response to stimuli of the usual type; it also responds, with a propagated wave of chemical action, to intermittent exposure to mitogenetic radiation from some other source. This so-called "mitogenetic excitation" appears after a latent period of 0.001 sec., is transmitted at a rate of 30 m./sec., and its nature varies with the nature of the exciting radiation. A single line from the glycolytic spectrum, of wave-length 217–218 μ , say, will set up a propagated disturbance involving emission of this same line, and, in addition, of other lines of the glycolytic spectrum—one, for example, at 190–192 μ . An interesting case, as Gurwitsch puts it, of "antistokes". A pure glucose solution, it may be mentioned, shows a similar secondary excitation which travels through the solution at a rate of 10–12 m./sec.

With regard to the behaviour of the central nervous system, Gurwitsch has studied the radiation emitted from the surface of the optic chiasma, the optic lobes, the hemispheres and the medulla of a frog stimulated visually. He finds that the "visual act" is accompanied by emission of radiation from all these regions; the stationary spatial distribution intensities in the cortex are a function of the nature of the stimulus—varying, for example, when a white visual field is replaced by a moving black pattern on a white ground, although a half white and half black field gives the same pattern, whether the black or the white portion forms the upper half. The spectra from the optic nerve and the hemispheres are also different with stimuli of different colours.

Sufficient has been said to indicate the general nature of Gurwitsch's experimental evidence, although it is not possible in a short review to deal with all its complexities, and surely not necessary to indulge in any lengthy criticism. Gurwitsch's discoveries speak for themselves, and the reviewer may be forgiven for taking to heart the author's advice, in a footnote dedicated to his critics, "to act more cautiously in the future, in order not to find themselves in a ridiculous position". He may nevertheless be allowed to suggest that the discoveries in question are open to serious doubt on physical, chemical and physiological grounds.

J. B. BATMAN.

The Nature of Human Nature:

and other Essays in Social Psychology. By Prof. Ellsworth Faris. (McGraw-Hill Publications in Sociology.) Pp. xii+370. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 21s.

AMERICAN sociology has been often described as suffering from two major though mutually exclusive complaints: a tendency to systematization which borders on vacuous verbosity; or, in contrast, a raw empiricism satisfied with increasingly detailed descriptions and the endless and aimless collection of fact, numerical in preference. On the whole, this indictment is as unfair as in a few exceptional cases it is amusingly apposite.

The present volume by one of the veterans of American sociology is a proof that Prof. Faris—and he represents the best and most numerous group of his colleagues—can be at the same time concrete and theoretically inspired; interested in facts, yet always infusing them with theoretical insight and human sympathy. The volume consists of collected essays ranging over a variety of subjects, and written over a period of years.

Some of the chapters are vigorously controversial. His robust, almost brutal handling of Pareto will be a delight to those of us who dislike irrational fashions in science (or pseudo-science) and quasi-religious cults in abstract sociology. The chapters on race and racial problems show once more the American mind at its best. Prof. Faris is, needless to say, strongly opposed to all extreme racial theories. He does not, however, dismiss the factor of race as a mere figment but deals with it in a truly scientific spirit. The group of essays on ethnographical subjects are based on the author's personal acquaintance with Central Africa, where he has lived for seven years. In his treatment of psycho-analysis and behaviourism, in the fundamental problem of human instincts in society and in his discussion of the Jewish question, we find everywhere an outspoken, honest, shrewd and at the same time, widely read and rarely cultivated mind. The book is written in simple and direct English; it is witty and full of vigour; it is as interesting as it is instructive; it vindicates the scientific character of American sociology.

B. M.

Comets:

their Nature, Origin and Place in the Science of Astronomy. By Mary Proctor and Dr. A. C. D. Crommelin. Pp. xi+204. (London: The Technical Press, Ltd., 1937.) 8s. 6d. net.

THIS work is written in simple and non-technical language and for this reason it will prove attractive to the general reader. The student of astronomy too will find it a most useful book, especially for references, as it supplies very useful information on famous comet hunters and also on the history of some of our well-known comets, Pons-Coggia-Winnecke-Forbes, Halley, Biela, Encke, etc. There is a description of the return of Halley's Comet in 1910—a return which caused considerable interest in the astronomical world especially, as Drs. Cowell and Crommelin had devoted a lot of time to the

computation of the perturbations by the planets. They predicted the time of perihelion passage as April 17, 1910, and this prediction was correct to less than three days.

Miss Proctor's father, Richard A. Proctor, showed many years ago that there were insuperable difficulties against the theory of the capture of comets by planets, and this is discussed in the present book. Dr. Crommelin supports Proctor's position and has devoted much attention to the view that the comets are not extra-solar. He agrees with Proctor that the short-period comets were expelled from the giant planets, but considers that Proctor was in error in postulating this expulsion millions of years ago. Crommelin believes that it took place in comparatively recent times—a view which is supported by the well-known fact that these short-period comets are rapidly disintegrating and last only a few centuries, not millions of years.

The book has a number of useful illustrations and an index is a great convenience. It is a very readable and interesting work. M. D.

Das Gallium:

eine kritische Würdigung der Erkenntnisse mit experimentellen Beiträgen. Von Dr. Erich Einecke. Pp. 155. (Leipzig: Leopold Voss, 1937.) 12 gold marks.

THIS monograph gives a detailed account of the element gallium, which is now available on the market. After a historical introduction, it specifies the sources of gallium and the methods of extracting the element from them. The physical and chemical properties of gallium and of its alloys and compounds, including organo-metallic compounds, and the analysis of gallium, are described with 450 references to literature and 15 patents. Since 1932 gallium has been separated from the by-products of the copper schist of Mansfeld by the Vereinigten Chemischen Fabriken at Leopoldsdahl, and the price is now about 10 marks per gram. The metal has a very low melting point, 29.78°, and remains supercooled much below 0°, and a high boiling point, so that its use in high-temperature thermometers in quartz has been the object of research. Gallium compounds have also found application in pharmacy. The book contains some original observations by the author and is a valuable survey of the present knowledge of gallium and its compounds.

Photography

By Dr. C. E. Kenneth Mees. Pp. xii+214+63 plates. (London: G. Bell and Sons, Ltd., 1936.) 7s. 6d. net.

IN January 1936 the "Christmas Lectures" at the Royal Institution were given by Dr. Mees. His book covers the ground of the lectures in a very readable and extremely well-illustrated way. The history of photography is fairly fully summarized in a chapter of thirty-three pages. Another chapter describes the manufacture of photographic materials. The remainder of the book deals with the principles and applications of photography.

Mechanics of Sport*

By Sir Gilbert Walker, C.S.I., F.R.S.

IN games with a ball in their most primitive stages, the ball may be simply a convenient lump to be thrown or hit; but effects of spin soon play their part. It is well known that Prof. P. E. Tait measured the starting speed of a golf ball and thought he had proved mathematically that its range could not be more than about two-thirds of the distance that his son proceeded to drive it. The cause lay in the upward force due to the under-spin, and the explanation of such an effect had been given by the late Lord Rayleigh, as well as in general terms by Sir Isaac Newton. Similar effects may be seen in a slice at golf, a swerve in cricket or baseball, or an American service at lawn-tennis.

Another game in which a swerve occurs is curling, and the path of a stone happens to have the same relation to its spin as that of a ball moving through the air. Now the bottom of a stone is not flat, but is hollowed, so that it is in contact with the ice over a circular line about 6 inches in diameter. Let us suppose that the direction of spin is such that the forward side is travelling towards the left. If we think of the sideways friction on the circle of contact, that in the front half of the circle is to the right and on the rear half to the left. Now the stone moves to the left, so the friction on the rear half must be the greater. But as the forward motion of the stone as a whole is retarded by friction on the ice, the pressure on the rear half must be less than that on the front half; and if the stone were moving over a glass plate the rear friction would be the less and the stone should swerve to the right. This actually happens. On ice, however, it swerves to the left and so there must be better lubrication on the front half, or greater pressure, than on the rear half. Now we know that when ice is not far from the melting point, pressure in excess of a critical value melts the ice and reduces the friction: it is this property that makes skating possible, for it produces a film of water between the skate and the ice. So there should be more melting in the front half; also a stone should refuse to curl when its pressure cannot melt the ice, that is, when it is very cold. This agrees with experience.

Curiously enough, there is yet another case in which rotation sets up deviation in the same direction as for a ball. It is that of a falling long strip of cardboard. As Maxwell pointed out, if a spin is started, the downward velocity will be

least after the plane of the strip has passed through the horizontal and greatest after passing through the vertical. So the couples tending to increase the spin will be greater than those tending to decrease it; and the spin will grow. Also the horizontal forces will be greater after the vertical position has been passed through, and the sideways motion will appear. An example of this may be seen in the bull-roarer, an implement used in magical rites by primitive men over a large part of the earth. When the bull-roarer is twirled round, the string describes a cone on the side indicated by the theory, and when it has twisted so far that it must start untwisting, the cone shifts over to the other side.

Some effects of the 'nap' of a cloth may now be considered. A billiards player learns by experience that the path of a ball travelling slowly with much 'side', that is with a rapid spin about a vertical axis, will be diverted to the right or left according as the spinning motion on the right side is with or against the nap. The deflexion may be something like an inch in the length of the table. I have seen pages of mathematical analysis vainly devoted to the subject. But if we state the result in the form that the path bends away from the side on which the nap is being rubbed up and toward that on which it is being rubbed down, the explanation is obvious; for on the rubbed-up side the effective surface is higher than that on the stroked-down side, and the ball moves, as it were, on an inclined plane.

Let us consider now some of the weapons of primitive people. Slings and stones are still widely used, but the range of an arrow or a throwing spear is much greater than that of a stone of the same weight starting with the same speed. A few efforts to throw a wooden stick five feet long by hand will show that, unless precautions are taken, there is a marked tendency for it to travel in the stable transverse attitude with its length at right angles to its path, so that the range is poor in the extreme. For steady flight with the axis longitudinal we must either provide resistance in the rear end, as in an arrow, or put the centre of gravity forward, or spin the weapon about its axis; in a throwing spear both the latter devices are commonly employed. The natural way to give the spin is by wrapping the thumb and fingers round the spear, so that it rolls off the hand on release. The assegai is thrown in this way, and flies like an arrow from a bow; its penetration is very great.

* Substance of a lecture delivered at Derby on September 6 in connexion with the British Association meeting at Nottingham.

In the course of time, primitive peoples have developed two devices for throwing, the spear-thrower and the beckett. The former is a stick about two feet long and in its use the spear lies along the spear-thrower with its butt resting against a projecting peg. This makes possible an invaluable flick of the wrist and, strangely enough, imparts a considerable spin. This would be impossible if the spear were not slightly 'whippy', so that an imperceptible flick to one side in its slightly bent state will apply a couple about its longitudinal axis. I believe that a range of 150 yards can easily be attained in this way.

The beckett is a short cord wrapped around the spear and also the first finger of the thrower's hand. It enables the wrist to be freely used and gives the valuable spin. The Roman *pilum* was thrown in this way with a thong called *amentum*.

A boomerang can to-day be looked on as an anticipation of the 'autogiro'; for as with the horizontal fan of the autogiro, its rotation provides support similar to that of the wings of an aeroplane. The couples necessary for its steering are produced partly by the warping of its plane and partly by the lack of symmetry in its cross-section. Returning boomerangs may describe paths of various types; we may have several circuits in front, or a figure of eight. But for an ordinary missile to be thrown at an animal, the shape is designed to give a straight and very flat trajectory. Its efficiency is considerable; when my range with a cricket ball weighing $4\frac{1}{2}$ oz. was seventy yards I could throw a straight-going boomerang weighing twice as much a distance of 185 yards. One of my literary friends used to maintain that a boomerang alighted rotating faster than when it left the thrower's hand; and I used to reply, with the cocksureness of a mathematician, that such a thing was impossible. But we are now familiar with the way in which, except in recent patterns, the rotation of the fan of an autogiro was provided, not by the direct drive of an engine, but by the forward rush of the machine through the air. So my literary friend was not far wrong.

A well-known tool of the Stone Age is the adze, of which the head, or celt, may have a curious property; when placed on a fixed plate of clean glass it may spin in one direction but not in the other. The celt is oval and at the point of contact with the plate the lines of curvature are not, in general, precisely parallel with the dynamical axes—the axes based on the distribution of matter. There is rotational asymmetry, and this shows itself when the celt is spun. Theory brings out another paradox; when tapped at one end rotation is set up, and the direction of this may be reversed merely by raising the centre of gravity.

Let us now turn to some problems of the motion of living beings. The art of swimming has been revolutionized by copying primitive peoples in methods so obvious that we ought to have thought of them. Thus in 1892 the record for the mile was 29 min. 25 sec.; it is now 21 min. 7 sec., an improvement of about forty per cent. In the crawl stroke the body is horizontal instead of sloping, so that the resistance is reduced and the energy is nearly all spent in propulsion, whereas much was spent in keeping the head out of the water. In it, also, useless resistance is not caused by moving the arms forward or sideways in the water, instead of backwards, and the legs, which are not well designed for propulsion, remain nearly straight; their movement, whether the flutter or the scissors, is made three or four times to one of the arms and has a very small range; its object is largely that of controlling the position of the body.

We will now consider a high jump. A good performer crosses the bar in a nearly horizontal attitude, so that as he approaches it vertically he would, unless something occurred, turn through another right angle in descending and alight nearly upside down. In fact he learns to make violent contortions to avoid a dangerous descent. Perhaps the best exponent of this art is the cat, which, if suspended by the paws with its back only a few inches above a table and released, will fall on its feet. It performs the whole operation of rotation in the air in about a quarter of a second. This can be illustrated by mounting a platform able to rotate without appreciable friction, when, by repeated use of the arms, a man can turn his body completely round as often as he wishes, although at no instant is there the slightest angular momentum about the vertical.

Another theme is that of sailing flight. In the tropics when the sun has sufficiently heated the earth's surface, we see kites and vultures flapping their way upwards until about fifty feet above ground; and then, having reached an up-current, their labours cease and they soar in spirals to a height of perhaps 2,000 feet; they may wander at will all day and descend at sunset. At the first glance it would appear from the inclination of the wings that the up-current would drive the bird backwards, not forwards, but on plotting the motion of the bird relative to the air and remembering that its wings are slotted the paradox is solved.

I believe that the mechanical efficiency of a modern sailplane easily beats that of a vulture, the flight of which is handicapped by carrying much flesh; so that in the tropics a skilful and experienced pilot should be able to roam all day at will. But even in our comparatively feeble European sunshine, the distance record is 313 miles and a height of more than 19,000 feet has been reached.

Tests in Common Use for the Diagnosis of Colour Defect*

By Dr. Mary Collins

THE testing of colour-blindness in all its forms presents a problem of great practical importance involving the adoption of a definite technique.

The spectrometer is undoubtedly the most fundamental test of colour vision, but it is seldom available for practical purposes, and the majority of tests, apart from those in scientific laboratories, are carried out either with some kind of lantern test or some kind of pigment test. There are various types of lantern tests available. The Edridge-Green colour perception lantern is the only one which has been used by the writer. A newer model is the Board of Trade lantern test, recommended with modifications by the committee set up to consider colour vision requirements in the Royal Navy. In using this the eyes have to be dark-adapted for 15 minutes. The Giles-Archer perception unit is also a new and simple model, and it, too, requires the eyes to be dark-adapted. These lantern tests, and many others, have the advantage that coloured lights are used instead of pigments, which brings conditions of testing nearer to everyday conditions in the Services, the railroad, navigation and aviation.

Certain pigment tests have also been extensively used, and it is these I should like to discuss in some detail. In some of these tests, it is puzzling to find mistakes made sometimes by individuals with normal colour vision which should only be made by colour-blinds. The printing of the tests may be partially to blame, but it must be recalled that decisions are constantly being made on the results from these tests, and therefore it is essential to recognize which responses are diagnostic and which can be ignored. In order to reach a valid basis for diagnosis, I have given a battery of tests under constant conditions of distance and illumination to an unselected group of about 340 candidates, exclusive of colour-blinds, applying to be accepted as apprentice printers. Their responses, therefore, to the tests may be compared with the responses of a group of colour-blinds tested under the same conditions. This normal group acts as a control group against which the results for each test used can be evaluated at its proper worth.

Owing to exigencies of space it will not be possible to discuss the details of the results obtained with all the tests which have been used. I can indicate the type of investigation under progress by giving the results from one of the tests only, "The Ishihara Tests for Colour Blindness" (5th Edition).

The Ishihara test is composed of a number of pseudo-isochromatic plates in which coloured numerals appear on coloured backgrounds. In some of the plates only part of a numeral appears to a person who is colour-blind, this being dependent on the colours used. For example, an 8 may be the numeral read by one with normal colour vision, but only part of it may be seen by the colour-blind, and he reads it as 3. Or a totally different numeral may be seen by the colour-blind from the arrangements of the spots before him, and instead of seeing a 5 as the majority would do, he sees a 2 standing out distinctly from the background. Further, in some plates, the position is reversed as it were, and although the person with normal colour vision sees nothing but a blur of colour, the colour-blind sees a numeral quite clearly. If one with normal colour vision looks at these plates through a blue glass, the 'hidden' numbers become visible.

The individuals forming the control group who were tested were found to vary markedly in their colour discrimination. It seemed advisable to divide them into two groups termed respectively *N* (normal) and *N-* (showing greater deviation from the normal). The classification is of necessity an arbitrary one because it is difficult to know where to draw the dividing line; in fact, the line of demarcation between colour-blinds and non-colour-blinds may itself vary according to the purpose in hand. In the report of the "Colour Vision Requirements in the Royal Navy", already referred to, it is stated of a certain test that if used alone it causes extravagant rejection of candidates who may be fit even for the seaman branch. This merely indicates that the standard for rejection can be changed in accordance with the post to be filled. It is interesting to note that three grades, so far as colour discrimination is concerned, are suggested in this report.

The colour-blinds in the present test have been classified thus because of their responses not to any single test but to at least six tests, and in some cases a spectrometric examination was also made. Similarly, in the *N* and *N-* groups, their allocation to these classes is based on the results obtained from the same battery of tests.

The accompanying table shows the results from the Ishihara test when given to these three groups. The percentage frequency of the responses in each group has been calculated with regard to normal responses and colour-blind responses. The table

*Continued from page 554.

is read thus: in plate 5, 56 per cent of group *N* read the figures correctly as the normal do, that is, read them as 74, whereas 11 per cent of group *N* read the figures as the colour-blinds do, that is, read them as 21. The frequency of responses other than normal and colour-blind has been omitted. In the *N*-group, 29 per cent gave the normal response, 31 per cent the colour-blind response. In the colour-blind group, 0 per cent gave the normal response, 81 per cent gave the colour-blind response.

ISHIHARA TEST.

Frequency in percentages of normal and colour-blind responses for *N*, *N*-, and colour-blind groups.

Plates	As read by normal	As read by C.-B.	Normal <i>N</i> . C.-B.	<i>N</i> - <i>N</i> . C.-B.	Colour-Blind <i>N</i> . C.-B.
1	12	12	100 0	100 0	100 0
2	8	3	100 0	100 0	40 55
3	6	5	100 0	100 0	21 71
4	5	2	99 5	92 4	12 74
5	74	21	56 11	29 31	0 81
6	2	—	99 0	83 1	0 100
7	6	—	100 0	96 4	5 96
8	5	—	100 0	96 2	5 96
9	7	—	100 0	100 0	2 96
10	—	5	91 4	80 6	0 96
11	—	2	72 27	28 48	0 100
12	26	2 } or 6 }	99 0	90 1	59 } 10 }
13	42	4 } or 2 }	100 0	100 0	55 } 26 }

The frequency of responses other than normal and colour-blind has been omitted.

N = 236 males; *N*- = 48 males; C.-B. = 45 males.

Plates 2 and 3 are never wrongly read by either the *N* or *N*-group, but Plate 3 seems the better diagnostic test of colour-blindness, as 71 per cent of the colour-blinds failed on it, and only 21 per cent passed. Plate 4 is equally good, although 0.5 per cent of the *N* group and 4 per cent of the *N*-group gave the typical colour-blind responses. Plate 5, which is read as 74 by the normal and as 21 by the colour-blind, is said by Miles to be "certainly the most sensitive indicator of colour weakness that we possess", and in the summary at the conclusion of the article, he suggests that in testing men for mercantile establishments only Plate 5 need be used at the original interview. It is also regarded in the "Report on Colour Vision Requirements in the Royal Navy" as one of the most searching plates. It is true that 81 per cent of the colour-blind read the figures as 21, and the others in different erroneous ways, but if we look at the results from the *N* and the *N*-groups, we must modify our opinion. Only 56 per cent of the *N* group passed, whereas 11 per cent failed, that is, read the 74 as 21. The remainder read the 7 as a 2 or as a 9 or as a 1, so that the figures read as 24 (7 per cent), or 94 (2 per cent), or 14 (1 per cent): or the 4 was read as a 1, and the numbers read as 71 (20 per cent), or 91 (2 per cent) or 11 (1 per cent). In the *N*-group, the

percentage of those passing is even smaller, 29 per cent, and the failures 31 per cent. The other variations also occurred. It may be, of course, that this plate offers a very delicate test of colour weakness, and therefore is very effective in picking out colour defect of varying degree. But sometimes it was the only error the individual made not only in this test but also in a group of tests.

The next four plates seem to be very significant. The normal group shows a perfect pass in all four and the colour-blinds almost a complete failure.

The next two plates containing the hidden numbers differ very much as regards efficacy for detection. The hidden 5 is certainly not visible to the normal eye, and the fact that 4 per cent with normal colour vision saw it easily is a curious result. These 4 per cent have perfect colour vision on all the tests, and one would be almost inclined to rate them as *N*+. Whether the supersensitive see the 5 or not requires further investigation. The 2, on the other hand, is not satisfactory. It could be seen fairly easily by all groups, as will be evident from the percentages quoted. Twenty-seven per cent of the *N* group and 48 per cent of the *N*-group were able to read it.

The last two plates are very satisfactory.

The Ishihara test is a very reliable test of colour-blindness and did not allow any of the colour-blinds to pass. It also seems to detect colour weakness in a highly efficient manner.

The results from this test may be sufficient to give some idea of the type of investigation which has been carried out. A similar analysis of the results obtained with other pigment tests—the Stilling, Schaaff's mosaic plates, the Nagel, the Podesta, the Edridge-Green, etc., leads to similar conclusions, namely, differences in the value of individual tests, inconsistencies in the findings arrived at with any single series, and so on.

There is a good deal of doubt whether we ought to speak of reliability and consistency in connexion with the results of this analysis. It may be that the discrepancies disclosed are due to the great variety of those deviations from normal colour vision which are so marked as to justify their being regarded from a practical point of view as cases of colour-blindness. This interpretation of the facts is to some extent confirmed by the results of filter analysis. Plates which all profess to diagnose deuteranopia, for example, show very differently under filter analysis, and similarly evoke different responses from different deuteranopes. The inference would appear to be that we are dealing not with linear variations in degree but with multidimensional variations. A wide new field for investigation is thus disclosed, the working of which may yield valuable results for the whole theory of colour vision.

Work of the Discovery Committee

FIFTH COMMISSION OF THE R.R.S. *Discovery II*

THE Royal Research Ship *Discovery II* is again on the point of departure from London for the Antarctic: she is expected to sail from St. Katharine Dock on October 7 and will be away from England for twenty months. During this time she will be continuing the research on the distribution of whales, hydrology and plankton, the progress of which has been the subject of the recent report referred to in *NATURE* of September 25.

The first seven months (the southern summer) are to be spent in making a circumpolar cruise planned to provide data for comparison with those obtained on the winter circumpolar cruise of 1932 and with those of the survey of the southern part of the Pacific Ocean in 1934. A circumpolar cruise in summer was started in 1935-36, but this was not completed as it was necessary to revise the programme after a voyage had been made to the Ross Barrier to pick up the American airman Mr. Lincoln Ellsworth.

Leaving Cape Town in November, the ship will steam south-south-east as far as the edge of the pack-ice. On the way southwards a full station will be worked every day: this includes temperature measurements and collection of water samples from a series of 22-25 depths between the surface and the bottom, and the fishing of fine and coarse nets vertically and obliquely down to a depth of at least 1,000 metres.

When the ice-edge is reached, a course will be set towards the east, but tacks will be made north-east and south-east so that the conditions in the warmer water of the open sea to the north of the pack-ice can be examined as well as those at the ice-edge itself. While the vessel is to the southward of the Antarctic convergence—the boundary between antarctic and sub-antarctic conditions at the surface—a constant look-out will be kept for whales; estimations will be made of the relative numbers of Blue and Fin whales seen, and some comparison will then be made of the relative abundance of whales in the different sectors.

In Antarctic waters special nets will be fished for krill (the food of whales) and particular attention will be paid to the collection of young krill near the ice-edge. Where the ice conditions allow the ship to reach the continental shelf, there will also be more intensive work.

In order to complete the circumpolar voyage, the ship must steam northwards to Australia and

New Zealand to replenish her bunkers with oil fuel, and she is expected to be in Fremantle late in December and in Dunedin early in February. Further supplies of fuel will be taken from the Falkland Islands and South Georgia. On both northward and southward voyages the routine observations—at least one full station daily—will be continued; they will give sections across the Antarctic, sub-Antarctic, and sub-tropical zones, and comprehensive data for further research on the problems of the meridional circulations of water and plankton.

In the Atlantic Ocean four lines of stations will be worked across the cold current which flows towards the east from the northern part of the Weddell Sea, and observations will be made between 0° and 20° E. in the current that flows westward into the Weddell Sea along the fringe of the Antarctic continent. The purpose of these observations is to obtain a substantial sample of the krill population in the Weddell Sea current.

The ship is expected to complete the circumpolar voyage and to arrive back in Cape Town early in May 1938, and she will sail southwards again, in midwinter, about July 1.

The second half of the commission will be spent in the eastern part of the Atlantic Ocean and the western part of the Indian Ocean, and repeated lines of observations will be made along the meridians 0° and 20° E. The repeated cruises will only differ in so far as they are affected by the position of the ice-edge, and great care will be taken to preserve a uniform method of making all the observations so that comparisons of the results of successive cruises will be as valid as possible. The work will include observations on whales; measurement of temperature, salinity, nutrient salt and oxygen concentrations between the surface and the bottom; intensive plankton fishing—particularly for krill—down to a depth of at least 1,500 metres; and meteorological observations and bird counts. It is hoped to repeat the cruise—southwards along 0°, eastwards near the ice-edge, and northwards in 20° E.—at least seven times before April 1939, when the ship will return to England.

The director of research, Dr. N. A. Mackintosh, will accompany the ship during the first part of the work, and the scientific staff will include Mr. H. F. P. Herdman and Mr. A. J. Clowes as hydrologists, and Dr. T. J. Hart and Mr. J. A. Nicholson as zoologists. Lieut. L. C. Hill, R.N.R., is again in executive command.

At the recent Imperial Conference the possibility was mentioned of some form of co-operation between the Dominions in any form of economic or scientific activities which might be undertaken in the future in the Antarctic. In this connexion the governments of South Africa, Australia and New Zealand have been invited to nominate scientific or other workers to sail with the *Discovery II*, each for a section of the circumpolar cruise, in order to study the methods of research used by the Discovery Committee.

WHALE-MARKING VOYAGE OF THE R.R.S. *William Scoresby*

The Royal Research Ship *William Scoresby*, the Discovery Committee's smaller ship, which is now used mainly for whale-marking, has already sailed, the purpose of her early start being to search for

whales in sub-Antarctic waters before they have reached the Antarctic feeding-grounds. The route to be taken depends largely on the abundance and movements of whales. Fuel will be taken, however, at South Georgia in November, and it is probable that operations will then be extended eastwards towards Bouvet Island if ice conditions are suitable. In the second part of the season the ship will move to more westerly regions, near the South Shetland Islands and in the eastern part of the Pacific sector.

The *William Scoresby* sailed on September 16 and is expected to return about April 15, 1938. Mr. G. W. Rayner is in charge of the operations and Lieut. R. C. Freamer in executive command.

Some four thousand whales have now been marked and more than ninety marks have so far been returned.

Genetics and Taxonomy

VARIOUS articles and letters that have appeared in *NATURE* during the past few years suggest that workers in special branches of biology (particularly in cytology, ecology, and genetics) are showing an increasing interest in the impact of their discoveries on taxonomy, and that this interest is shared by their taxonomic colleagues. Papers and discussions at the annual meeting of the British Association may also frequently be accepted as an indication of what subjects are developing in scientific favour. At the recent meeting at Nottingham a morning was devoted by Section K (Botany) to "Genetics and Taxonomy", with a rather wider range in the papers and discussion than is suggested by this general title.

It would appear from Dr. W. B. Turrill's opening paper that plant taxonomy is to some extent at the cross-roads. The old orthodox (or 'alpha') taxonomy, based largely or entirely on morphology, has remarkable achievements to its credit and there is still much to be done by its traditional methods, especially in the floras of the botanically less explored parts of the world. On the other hand, the new methods, especially those with an experimental basis, are leading to the discovery of important characters or attributes, many essentially physiological, which show that the old classification needs improvement or even altering fundamentally if it is to be of the widest use. Cytogenetical investigations, while not the only lines of research which are making contributions to a new taxonomy, are of very considerable

value since they are throwing light upon the following problems which concern the taxonomist: the degree of plasticity of the genotype, the occurrence and constancy of correlation of characters, the occurrence and nature of sterility barriers, the evaluation of characters, the recognition of hybrids, and the phylogeny of species. Examples illustrating the influence of experimental investigations on taxonomic concept, with reference to the above problems, are furnished by the research at Kew and Potterne on species of *Ranunculus*, *Silene*, *Centaurea*, *Anthyllis*, *Plantago*, and other genera.

Not infrequently modern investigations support morphological classification, as Mr. W. J. C. Lawrence showed for the genus *Dahlia* and Dr. K. Blackburn for *Silene*. For an increasing number of genera, cyto-genetical and biochemical analyses enable rapid and precise comparisons to be made between species, thus providing the taxonomist with a further measure of the relationship and evolution of species. The work at the John Innes Horticultural Institute on *Streptocarpus* and *Delphinium* serves as an example.

In such a group of plants as the grasses, taxonomists have sometimes attached undue importance to easily observed but relatively inconstant characters. Dr. T. J. Jenkin suggested the desirability of close co-operation between the taxonomist and cytogeneticist in elucidating the history and behaviour of pasture grasses and thus preparing the way for a better general classification of these economically important plants than at present

exists. Problems of interspecific and intergeneric hybrids are the concern of both the cytogeneticist and the taxonomist, as is also the determination of phylogenetic relationships. The taxonomist has to evaluate the characters he uses, making some of generic, some of specific, and some of varietal value, and so on. In *Lolium*, genetical research shows that height has little value as an indicator of relationships and specific distinctness, since a plant two inches high may be a sib to a plant twenty inches high. In the genus *Dahlia*, corolla colour definitely characterizes two groups of species and the wide colour range shown by the garden *D. variabilis* is, in agreement with other evidence, a witness to its origin as a hybrid between species of the two groups. Such examples of recent research illustrate the help the taxonomist may expect from the biochemist and cytogeneticist in his attempts to classify plants that the classification is not only widely useful but also indicates relationships.

In return for such help the taxonomist can assist his colleagues not only by identifying their original material on the basis of 'alpha' taxonomy, but also by indicating problems which are recognized as unsolved by the older methods. Prof. J. R. Matthews gave examples of closely allied species which were probably derived from a common ancestral stock but which have now a different geographical range. Cytogenetic research on such plants as *Ranunculus Flammula* and *R. reptans*, *Callitha palustris* and *C. radicans*, *Primula farinosa* and *P. scotica*, combined with other methods of investigation, might lead to the formulation of general views regarding the influence of isolation in speciation. Knowledge of the origin of the geographical race or subspecies may well give us a more complete knowledge of the origin of species.

The results of modern lines of work are beginning to influence taxonomic thought by making taxonomists consider the logical basis of their classification. There seems a general agreement that 'alpha' taxonomy (based essentially on morphology) should be maintained for the present. Subsidiary classifications, often based on a very limited and deliberately abstracted number of attributes are, however, essential for special purposes and especially for deductions from correlation of attributes. Such a classification as that of Turesson, which was ably advocated in the discussion by Dr. J. W. Gregor, has a considerable value both as a means of stating and comparing the results of eco-genetical research and as a guide in the practical application of such research to agriculture. Such special classifications, however, cannot replace a more general one, and exactly how far they can be combined with morphological criteria to lead to a practical and logically sound classification is a matter for continued experiment. As Dr. Turill said: "by trials and errors this 'experimenting taxonomy' will enable, one hopes, orthodox relatively stabilized taxonomy to incorporate new data and so to advance, gradually and cautiously, from an alpha position towards a far-off omega perfection of the classification of all biological knowledge".

The formation of the Association for the Study of Systematics in Relation to General Biology (see NATURE, July 24, 1937, p. 163 and Aug. 7, 1937, p. 211) was cordially welcomed at several sectional meetings of the British Association. It has evidently awakened considerable interest amongst biologists and should do much to stimulate and co-ordinate research into the many problems of equal importance to taxonomists and their colleagues in other branches of biology.

Obituary Notices

Prof. Albert Heim, For. Mem. R.S.

THE news of the death on August 31 at the age of eighty-eight years of the veteran geologist Albert Heim, though not unexpected, comes as a sad shock to many admirers. A very great man has gone, and a treasured connexion with the early days of Alpine structural interpretation has at last been broken. As a student, Heim came under the spell of Arnold Escher von der Linth, an open-air researcher, a great talker, but no writer. Heim loved the mountain side no less, but fortunately he was an artist, excelling with both pen and pencil; and in his early publications he preserved in truly glorious fashion Escher's discoveries, enriched by numberless observations of his own. Heim's technical skill was such that he

himself engraved the copper plates of many of the illustrations that adorn his text.

The great drama of Heim's scientific life had its origin in one of Escher's favourite ideas, the 'double fold' of the Glarus. In 1841 Escher argued for the existence of 'colossal overshoving' of older rocks on to younger in the Canton of Glarus. He wanted to make the displacement involved as small as possible, and, as the cover of older rocks was discontinuous, he presently imagined that he could explain their situation by postulating two shoves from opposite directions, each with rather less than half the magnitude required if the shove were single. Heim adopted this theory in his classic "Untersuchungen über den Mechanismus der Gebirgsbildung", published in 1878;

and he maintained it for many years in face of slowly developing opposition.

We may recall Marcel Bertrand's paper unifying the movement in 1884, Suess's conversation with Heim in the same sense in 1892, and Schardt's one-way interpretation of Pre-Alpine tectonics in 1893. Schardt's revolutionary ideas led on to Lugeon's synthesis of Swiss Alpine structure considered as a whole, published in 1902. Lugeon was a pupil of Heim's, and while his masterpiece was passing through the press he received a noble letter from his old professor, in which the latter confessed that he now favoured Bertrand's interpretation and expressed joy at the new vision that had come.

The marvel of Heim's career is that it began in early youth and culminated in old age. When only twenty-four years old, Heim succeeded to the chair of geology at the Polytechnic in Zurich, and in the following year to that at the University of the same town, and held both posts until 1911; and yet, in 1919-22, he produced his three-volume "*Geologie der Schweiz*", the finest national text-book that is ever likely to be written.

Heim was keenly interested in many aspects of geology besides tectonics. Here there is only room to mention his work on glaciers, of the erosive powers of which he did not have a high opinion.

Heim became a member of the Swiss Geological Commission in 1888, and directed its activities from 1894 until 1925. With C. Schmidt he published a very valuable map of Switzerland on the scale 1:500,000. He received honorary doctorates from Bern, Oxford and Zurich, and was elected a foreign member of the Royal Society of London. He has left a distinguished son, Arnold, called after Escher, who was truly helpful to his father during the latter half of his long life's work. E. B. BAILEY.

Lord Rothschild, F.R.S.

In Lionel Walter Lord Rothschild, who died on August 27 at the age of sixty-nine years, a scientific worker has passed away of whom it may justly be said that he was better known at home and abroad than any other contemporary zoologist. It was inevitable that a Rothschild deeply interested in biology and possessing large zoological collections which he was indefatigable in increasing for the benefit of science, should inspire the imaginative Press of many lands to publish fanciful reports, which gave him a publicity often very embarrassing and inundated him with offers of collections and service and with requests for help. But he would have gained high distinction in science without a family name already world-famous. His interest was so intense and so wide, his ever-ready support of science so valuable and his scientific publications so important, that he held a high place of honour in zoology and was elected an honorary fellow by many foreign scientific societies. Entomologists, ornithologists, herpetologists and mammalogists all claimed him as one of their own.

Being of delicate health as a boy, Rothschild was educated at home and then spent some years at Bonn and Cambridge, following all the time his great love for natural history. The boyhood collections of Lepidoptera and Coleoptera increased to such an extent that in 1889, when he became of age, he built a cottage at Tring for the safe housing of the collections, and soon after a public museum in which were exhibited mounted specimens of all classes of animals. Following family tradition, he entered the bank of Messrs. N. M. Rothschild and Sons to study finance, which left him little time for the supervision of the growing collections. In 1892, on the recommendation of Dr. Albert Günther, he put Mr. Ernst Hartert, the ornithologist, in charge of the collections, and six months later entrusted the Evertebrates to the care of the writer of the present lines. It became the definite policy gradually to build up in the research department collections of birds and Lepidoptera as complete as possible, and to increase the public department as resources permitted.

In 1888, Rothschild had bought a collection of New Zealand birds from Sir Walter Buller, and he became so interested in the fauna threatened by the spread of the white race that he sent a bird-collector to the Sandwich Islands, took up the study of the giant tortoises restricted to the Galapagos and Mascarene Islands, and of marsupials, and supported all measures for the protection of animals and plants by the creation of Nature reserves. His reputation as a zoologist was established before he was thirty years of age. In 1898, the University of Giessen conferred upon him the degree of Dr. phil. and in 1899 he was elected a trustee of the British Museum. He gave up finance in 1908 and then could devote himself entirely to science and to civic duties. From 1899 until 1910 he represented Mid-Buckinghamshire in Parliament, and in 1911 he was elected a fellow of the Royal Society in recognition of his services to the natural sciences. He travelled a good deal in Europe and North Africa, but being a bad sailor never visited the tropics. On the death of his father in 1915 he succeeded to the title.

At the time of Lord Rothschild's death the buildings of the museum had an aggregate floor-space of nearly an acre and a half. The public department now contains more than 2,000 mounted mammals, among them 13 gorillas, 25 chimpanzees, 24 echidnas, more than 200 marsupials; among the 2,400 mounted birds there is a magnificent series of 62 cassowaries, the great auk and other extinct species. The research department lost in 1932 the collection of 280,000 bird skins, which a sudden heavy call on his finances compelled Lord Rothschild to sell; the large collection of eggs contains the best series in museums of eggs of birds of paradise and two great auk eggs; but the greatest asset is the collection of some two million Lepidoptera invaluable for the study of geographical variation and other problems of evolution. The collections were placed with great liberality at the service of scientific workers, who always found a cordial welcome at Tring. The museum is left to the trustees of the British Museum.

KARL JORDAN.

President Masaryk

By the death of Prof. Thomas Garrigue Masaryk on September 14, Czechoslovakia has lost its first president and the world is deprived of an eminent and much-respected philosopher and statesman.

Thomas Masaryk was born of humble Slovak parents at Hodonín, Moravia, on March 7, 1850. He had a chequered boyhood and youth. A primary school inspector secured for him the consent of the authorities to allow him to attend a secondary school to train for a teaching post. His parents' poverty, however, made it necessary for him to earn his living, and he was apprenticed first to a locksmith in Vienna and then to a country blacksmith. A former teacher arranged for his return to school, and in 1865 he entered Brno Grammar School. He made good progress, but his passion for truth brought him into conflict with the authorities, who forced him to leave. Fortunately, he was able to continue his studies at Vienna where, in 1878, he graduated as a doctor of philosophy.

A work on hypnotism in 1880 was followed by "Suicide and Modern Civilization" (1881). It was an analysis of causes of the high number of suicides recorded in Central Europe, and attracted attention both at the time and later. This philosophical study secured for Masaryk a Vienna lectureship, but in the following year he was made a professor at Prague. In 1885 he completed a lengthy work, "Concrete Logic", having previously written several shorter philosophical works, which were also translated into German. His later books mostly took on a political aspect. Thus "The Czech Question" appeared in 1895, and the "Philosophical and Sociological Foundation of Marxism" in 1898. Besides writing for the literary and philosophical journal, *Čas* (Time), which he founded, he kept in touch with science sufficiently to contribute a weekly scientific column in the Prague newspaper, *Národní Listy*. He did not identify himself with blind nationalism, and his scepticism (justified as investigation proved) of the genuineness of some alleged old Czech manuscripts brought him much abuse.

From his philosophical studies he was led to the formation of a 'Realist Movement' amongst educated Czechs. This was "an attempt to popularise the whole realm of Science and Philosophy. Without distorting scientific exactitude, Realism strives to render science accessible to every class of the people. It is a protest against the monopoly of learning, its endeavour is to socialise scientific learning and philosophical culture".

In 1878 Masaryk married Miss Charlotte Garrigue, a distinguished American, and incorporated her name in his own. She entered ardently into all his work until her death in 1923. They paid several visits together to England, America and Russia, and Prof. Masaryk continued to write many philosophical works dealing particularly with modern problems. He entered the Austrian Reichsrat as a 'Realist' in 1902, and rapidly made a reputation for honesty and uprightness, and he was quick to express his dissatisfaction at the methods practised, it appeared, by

all parties. His realism was a reaction against this and against the Tolstoyan slavonic philosophy of non-resistance to evil. Just before the Great War he wrote "The Philosophy of History and Religion in Russia", one of the most important books on the subject, whilst after the War he described his work for Great Britain and the allies and for the liberation of the Slavs. He was, for a time during the War, a professor at King's College, London.

On October 28, 1918, the Czechoslovak Republic proclaimed its independence with Prof. Masaryk (still in exile) as its first President. He held this post until December 1935, when he relinquished it with the recommendation that his younger collaborator, Dr. Eduard Beneš, be elected to succeed him. During the seventeen strenuous and difficult years of his term of office, Masaryk gave very active support to many educational movements. The new University of Brno was named in his honour, whilst the Masaryk Academy of Work, which concerns itself with supplying funds for researches in pure and applied science and in securing publication of the results, received his very keen approval and valuable support. Masaryk was in no small measure responsible for many educational advances associated with his country. Through his ministers, he was able to institute an enlightened policy advancing not only the hitherto restricted culture of the Czechoslovaks themselves, but also not overlooking the needs of the German, Hungarian and Polish minorities living within the frontiers of Czechoslovakia.

Prof. Masaryk leaves a son, Mr. Jan Masaryk, the Czechoslovak Minister Plenipotentiary in London, a married daughter and Miss Alice Masaryková, who had been his companion during the last years and is well known for her Red Cross and humanitarian activities.

G. D.

Mr. F. A. Potts

We greatly regret to record the death in London on September 15 of Mr. F. A. Potts, University lecturer in zoology and fellow (formerly tutor) of Trinity Hall, Cambridge. He was a member of a remarkable group of young men who were specialising in zoology at Cambridge in 1906-8, his group including Prof. W. E. Agar (Melbourne), the late Dr. W. S. Perrin (London Hospital) and the late Rev. S. A. McDowall (Winchester). In his final examination he obtained first classes in both zoology and geology, being one of the last students to obtain the double honour.

Mr. Potts, after visits to Naples and Plymouth, then settled in Cambridge, assisting in the teaching of the Zoological Department until the outbreak of the Great War. During this period he became well-known for his activity in the then rather modern lines of research. He directed his interest first of all to the effects of *Pellogaster* and *Sacculina* on their crustacean hosts, *castration parasitism*, extending this to a general consideration of phenomena associated with parasitism. His next investigations were devoted to the Rhinocophalan *Myxosomorphs* and to Nematoda, here a notable research dealing

with the free-living, hermaphrodite species. In 1913 he commenced an association with A. G. Mayer which continued until the latter's death in 1923. He several times visited the Carnegie Station off Florida, and in 1913 joined the Carnegie Expedition to Torres Straits. This association produced three important researches, now almost classical, namely: on the Rhizocephalan genus *Thompsonia*, which gave suggestions as to the evolution of the group; on the crabs forming galls in corals, including a study of their modes of life and their adaptations; and on the Crustacea, Ophiurans and Polychaets in association with the Crinoids of coral reefs. A post-War visit to Samoa and to further coral reefs was responsible for studies of rates of growth, of Cirripedes and other forms. In addition to the above, there are a series of papers dealing with the systematics of Polychaets of the Indian Ocean and an important study of *Teredo*.

On the outbreak of the Great War in August 1914, Mr. Potts was much exercised as he had been brought up to abhor war—but he felt strongly the devastation of Belgium and Louvain. His brothers had families and could not serve; therefore he must play the family's part. He at once put himself in training and in November almost "coerced" the colonel of one of the Duke of Wellington's West Riding battalions to give him a commission as he "had to get out to the trenches before Christmas". He was a great success, keeping the men cheerful, and on the formation of a machine gun section was placed in charge "because he knew all about science". He was there on the Western front for four years—and the writer, knowing his upbringing, his psychology and his extraordinary powers of imagination, feels that here was the highest form of courage.

Mr. Potts was a man with a host of friends, whose sympathy will go out to his widow and son. He was always cheerful, bright, happy, helpful and full of fun. In his teaching he dealt with every grade of student and liked to undertake new courses; his special subjects were worms and molluscs. He was thus eminently suited to the production as editor of that text-book on "The Invertebrata", in which he was associated with Borradaile, Eastham and Saunders, and to which he devoted the last years of his life.

J. S. G.

Prof. J. E. Duerden

THE death of Prof. James Edwin Duerden, which occurred on September 4 as a result of a fall sustained on his way to attend the meeting of the British Association at Nottingham, removes a man who has rendered devoted service to science in many fields.

Prof. Duerden was a student at the Royal College of Science, South Kensington, during the years 1885–1889, and obtained his associatehip of the College in zoology. His first appointment was as demonstrator in biology and palaeontology at the Royal College of Science, Dublin, where he developed an enthusiasm for marine work, resulting in valuable published contributions to knowledge of the Hydroids and Polyzoa of the Irish coast. During this time, he was appointed

a member of the Irish Fishery Survey. In 1895 he accepted the position in Jamaica of curator of the Museum at Kingston. Here he commenced a series of studies of the Actinaria and corals of the West Indies. He pursued his investigations into living and fossil corals at the Johns Hopkins University, Baltimore, U.S.A., and was appointed Bruce Fellow there in 1901.

The value of Duerden's work was recognized when the Carnegie Institution of Washington granted him facilities for the study of European fossil corals, and he was also selected as leader of an expedition to the Hawaiian Islands to study Pacific corals. He was soon recognized internationally as an authority on the structure and development of corals, and became assistant professor of zoology in the University of Michigan. In 1905, he was appointed professor of zoology in the new Rhodes University College, Grahamstown, South Africa. Whilst there, he was placed in charge of ostrich investigations for the Government. He quickly became an authority on the development of ostrich plumes and showed how the serious defects known as bars in the feather were produced by a reduction in blood-pressure during the night period. After the slump, in 1913, of the ostrich plume industry, he became interested in the scientific aspect of wool production, and was appointed Director of Wool Research in the Dominion, whilst retaining his professorship at Grahamstown. He was a pioneer in work on the assessment of quality in the fleece and studied the embryology and evolution of the South African merino fleece.

Duerden served successively as president, member of council and honorary secretary of the South African Association for the Advancement of Science. He retired from Grahamstown in March 1932 and became an honorary member of the staff of the Wool Industries Research Association at Torridon, Leeds, in May 1932. Here he followed up embryological work on the coats of British sheep, specializing on follicular arrangement, and arrived at important conclusions on the specificity of the follicle. At the time of his death he was collating his results prior to publication. His enthusiasm and personality made him a delightful colleague and an inspiration to all who worked with him.

We regret to announce the following deaths:

Prof. D. H. Bergey, formerly professor of bacteriology and hygiene in the University of Pennsylvania, known for his work on food preservation, on September 5, aged seventy-six years.

Prof. H. H. Collins, professor of biology in the University of Pittsburgh, known for his work on mammalian anatomy, on August 31, aged fifty-two years.

Prof. Adolf L. F. Lehmann, in 1909–30 professor of chemistry in the University of Alberta, and earlier associated with the Department of Agriculture of Mysore, on September 27, aged seventy-three years.

Senator Alessandro Lustig, formerly professor of general pathology in the University of Florence, known for his work on bubonic plague and sanitation, on September 23, aged seventy-nine years.

News and Views

The Globular Corona

THE sensational and distorted press comments on the coronal photographs secured from the stratosphere at the total eclipse of the sun last June, to which reference was made in *NATURE* of August 21, p. 310, have now been followed by more reasoned statements about the photographs. They amount to this: the photographs show more clearly to the eye what the measurements of von Klüber (*Z. f. Astrophysik*, 3, 159; 1931) and others have already proved, namely, that the successive isophotes of the corona round the sun are nearly circular. Graff, Bergstrand and Ludendorff were early workers in the same field of study and they have shown the differences in the behaviour during the solar cycle of this more regular corona and the superposed streamers. That some essential difference exists in the nature of the two main constituents of the corona was shown by the difference in the polarization between the inner corona and the streamers noted by Newall so long ago as 1905 and referred to again in a letter by K. G. Zakharin which appears in this issue of *NATURE* (p. 586).

The Storstrøm Bridge

A SHORT history and description of the Storstrøm bridge connecting the Danish islands Falster and Møn, which was opened by King Christian X on September 26, appears in *The Times* of September 25. Møn was linked up with Zealand by the Mønsund Bridge constructed in an earlier section of the bridge building programme initiated in 1933. The Storstrøm Bridge, which crosses an arm of the Great Belt, curving in a wide sweep of more than two miles, has been built for the Danish State Railways by the British firm, Messrs. Dorman Long and Co., Ltd., and completed seven weeks before the scheduled date. In its construction, the new 'chromador' steel, which has improved corrosion-resisting properties, has been used. The bridge has three navigable spans, the centre one 430 ft. in length and with about 80 ft. headroom, and forty-six shorter spans in the approaches. Tidal conditions, pack-ice and sea-scur were provided for by new and ingenious methods adopted in the building of the concrete and granite piers and in the erection of the steel girders. The bridge is described as being of a slender appearance but having a magnificence which can best be appreciated when the aluminium coloured steel is viewed in the morning sunshine. It provides a carriage way, a foot and cycle track, and a single line of railway on which trains can pass at a speed of 50 miles per hour. It completes the railway link between the Continent and Scandinavia for, by its opening, trains or cars can now run, via Warnemünde train-ferry, from Hook of Holland, Paris and Berlin, direct to Copenhagen, whence they can proceed by another train-ferry to Malmö, so that the Danish route now

compares favourably with that via Trelleborg-Sassnitz. It has the additional importance that it makes possible the extended use of modern streamlined 'lightning' trains in consequence of the longer journeys now undertaken.

Bimillenary of the Emperor Augustus

ON September 23, Signor Mussolini inaugurated the celebration of the bimillenary of the Emperor Augustus Caesar, who was born on September 23 in the year B.C. 63, by declaring open the "Augustan Exhibition of Romanism". Great Britain was represented by delegates from the British Museum, the Society of Antiquaries of London, the Societies for the Promotion of Hellenic and Roman Studies, and the University of London. The assistance which had been given by Great Britain in the preparation for the exhibition was generously recognized by Prof. G. Quirino Giglioli, who has been responsible for its organization—the work of five years. Nor does this long period of preparation seem excessive, when the vastness of the field covered by the exhibition is taken into consideration. Not only do they illustrate every side of life and culture of the city of Rome itself as the centre of the Empire, but they also include reproductions of the most remarkable monuments Rome has left in other parts of the ancient world. Further, they cover the religions, the arts and the material culture of the many and varied peoples who came under the sway of Rome, as well as trace in a special section the rise and growth of Christianity from the birth of Christ down to the Edict of Constantine. In this aspect the exhibition has a double significance for the archaeologist and the historian. On one side it emphasizes an internal mobility of peoples and cultures, which at a momentous phase in the history of civilization brought about such an interchange of beliefs and ideas as that, for example, which left for the contemplation of later generations a characteristic emblem of the eastern Mithraic cult in north Britain below the Roman Wall. At the same time, from the other side, it demonstrates the solidarity of the Empire, as against the rest of the ancient world, which has set its seal on European peoples, the heirs of imperial culture, no less effectually than the more familiar contrast of East and West.

Racial History in the Arctic

DR. ALBIS HEDLÖKA, of the Smithsonian Institution, Washington, D.C., on his recent return from his ninth expedition of anthropological investigation in the arctic regions of North-West America, has issued through the Smithsonian Institution a preliminary report on the results of his season's work in the Aleutian Islands, in which he discusses the character and distribution of early racial types in the Far North. The investigations and excavations carried out by

Dr. Hrdlička in 1936 and 1937 have been directed more particularly to the study of the problem whether racial migration from Asia, in addition to the Bering Sea route, may have made use of the more southerly passage by the Aleutian Islands—a suggestion which on a general line of argument would appear to have much to support it, but for which until recently positive evidence has been regarded as inadequate. In the expedition of 1936, it may be remembered, evidence was obtained which was held to support Dr. Hrdlička's view. Skeletal material and a large quantity of archaeological material accruing from the expedition's excavations in 1937, and now awaiting further detailed examination in Washington, Dr. Hrdlička holds, confirm his previously formulated theories, and afford him a basis for the racial classification to which reference is made above. "The finds," he states, "make more probable than ever the hypothesis of a 'race nursery' in the Far North for the aboriginal population of the New World."

BRIEFLY, Dr. Hrdlička's preliminary conclusions are that the present-day Aleutians, a broad-headed people, who do not fall precisely into either an Indian or an Eskimo classification, were preceded by an oblong-headed race, who had a much longer occupancy. This race he regards as the same as that which he discovered in the deepest parts of his excavations on Kodiak Island in 1931-35; while a similar type has been found in the lower layers of a mound at the mouth of the Frazer River, British Columbia. There are indications that this stock may have spread so far south as California. The Aleuts cannot be regarded as descendants of this people, and may, in fact, represent a backward migration from Alaska towards Asia. Dr. Hrdlička is now prepared to recognize in the North-West, not one or two racial types, as previously held, but five distinct, though basically related strains, as follows: (1) the long- and high-headed Eskimo of the Seward Peninsula, Barrow, and eastward along the arctic coast to Labrador and Greenland; (2) the broad-headed and medium-vaulted Eskimo of the Bering Sea coast and along the interior rivers from the Yukon southward; (3) the Aleuts with broad heads and low-vaulted skulls; (4) the Alaskan Indians; (5) the oblong-headed pre-Aleuts, whose remains were found by the expedition in the exploration of the past season. The archaeological finds included a new stone industry belonging to this people.

"Minnesota Man"

FURTHER investigations by Prof. A. E. Jenks in the northern lake area of Minnesota, from which were obtained the skeletal remains described elsewhere in this issue of NATURE (see p. 596) have brought to light evidence of what would appear to be an extensive camping ground of early man. From a kitchen midden buried some three feet under a bog of grasses and marsh weeds in Itasca State Park, Prof. Jenks has excavated some two thousand knife-marked bones, with knives of stone and other implements of both stone and bone. The bone bed varies in

thickness up to about four feet five inches. Associated with the bones of bear, elk, caribou and other big game animals in the kitchen refuse are the remains of an extinct form of bison (*Bison occidentalis*), confirming the early character of the site and the early date of its occupation by man. Prof. Jenks states in *Science* of September 10 that of five stone artefacts recovered from the bone bed, three are flake implements with retouch, while two are chopping tools, chipped to rough parallel faces, and retouched on the cutting edges.

Roman Jerusalem

THE discovery of an interesting and important relic of the Roman occupation of Jerusalem is reported. The Department of Antiquities, it is stated by the correspondent of *The Times* in the issue of September 28, while conducting excavations in connexion with the plan of the municipality for clearing away buildings from the Damascus Gate, has brought to light a Roman moulded plinth ten feet high, of which the top was found at a depth of thirteen feet below the surface. The plinth consists of massive blocks of stone, which, it is said, recall the finest work of the Roman period. The site has been identified provisionally with the city gate beside the "Women's Towers", mentioned by Josephus. It is hoped that excavation will be carried further in the expectation that it will throw light on the much-discussed problem of the Third Wall of Jerusalem.

Brood Diseases of Bees Investigations

EARLIER in the present year an appeal was made to beekeepers and beekeeping associations to support financially the continuation of the research on brood diseases of bees at Rothamsted Experimental Station. This work had been carried on for three years by Dr. Tarr with funds half of which were provided by the Government and half by the British Beekeepers Associations. The results of the first three years' work were so promising that it was unanimously decided by the Bee Research Advisory Committee at Rothamsted to continue for a further period of three years if possible. The estimated cost is £550 per annum, of which the Agricultural Research Council has promised £300, if £250 per annum can be raised from other sources. As the result of the appeal a sum of £226 has been received for the current year, which leaves a balance of only £34 to be made up. For the two following years, there is only at present a guaranteed fund of £103 per annum.

THE work carried out up to the present has already cleared up many difficult points. Dr. Tarr has shown that European and American foul brood are two distinct diseases caused by different organisms. He has confirmed that American foul brood is due to a bacterium, *Bacillus larvae*, and that its incidence is independent of the strength of the colony. European foul brood, on the other hand, is a disease of weak stocks and is probably caused by *Bacillus pluton*, in association with other organisms. He has also shown that a third condition known as 'addled brood' is

very prevalent in Britain; it constituted about one third of the cases of so-called foul brood sent in for examination. It is liable to be mistaken for foul brood, but is really due to a defective condition in the queen, and once it is recognized can readily be cured by requeening. The work in the next three years will be concentrated on tests of control measures for both European and American foul brood and further work on the organisms causing European foul brood. It is to be hoped that further support will be forthcoming to supply the small amount still required for this year's work, and that as many contributors as possible will continue to subscribe for the three years.

Regional Planning in the United States

A broadsheet issued by PEP (Political and Economic Planning) describes some developments in regional planning in the six New England States of the U.S.A. which are of some interest in relation to the Special Areas Bill in Great Britain. The broadsheet is based on a report prepared by the Commission on Regional Planning for New England, issued last year by the National Resources Committee, a progress report, "State Planning, Vermont", issued by the State Planning Board of Vermont, and on general reports on "State Planning (Review of Activities and Progress)" and "Regional Factors in National Planning", both issued by the National Resources Board. While the population of the United States as a whole increased by more than 140 per cent between 1880 and 1930, that of New England increased by little more than 100 per cent and that of the State of Vermont by less than 10 per cent. Seventy-seven per cent of the New England population is now urban, and only 6 per cent remains on farms. Simultaneously, the occupied population has declined to 42 per cent (as against 47.2 per cent in England and Wales), the long established shrinkage of employment in agriculture, forestry and mining being accentuated by contraction of employment in manufacturing and mechanical industries. These contractions are balanced by expansion of employment in trade, transport, professional, public, clerical, domestic and personal services.

A significant feature is the large increase in part-time farmers, and about one third of the area is still in farms. Attempts are being made to classify farms in relation to their suitability for profitable agriculture. It is anticipated that expansion of milk production on the better farms, for example, would more than make good any loss through winding up uneconomic holdings. The problem of the hill districts is also being tackled by a programme of woodland development and especially in planning for recreation. In building up a recreation industry, whether in relation to preservation of scenery and amenities, alliance between recreation and forestry, sports, improved communications, New England developments have perhaps most to teach Great Britain, and especially in regard to planned instead of piecemeal development. The Planning Boards in the

six States only date from 1935 and the six chairmen with an independent chairman and two co-opted citizens, make up the New England Planning Commission, which is assisted by consultants, a small staff of technical assistants, and an advisory committee of 546 members distributed throughout New England and representing all types of activities—housing, transport, town planning, industry, etc. This Committee does not meet as a whole.

Future of Air-Conditioning

IN the July number of *Water Works and Sewerage* the editor makes some timely comments on the future of air-conditioning. Apparently water supply managers have little definite information as to the probable demands on local water supply facilities that will be made in the near future. Another important problem that has to be considered is the question of sewerage facilities capable of handling the increased loading to be imposed in the form of spent water discharged from the cooling equipment into sewers that have not been designed for this load. At the recent convention of the American Water Works Association some interesting data were given. During the year 1935-36, the air-conditioning capacity installed had increased 35½ per cent in Chicago. During the same period, the water sold to air-conditioned premises had increased 38 per cent. The figures also show that the peak demand for a district which is now only 16 per cent air-conditioned is 130 per cent above the daily average demand. In July and August also, the demands per 24 hours in the districts most densely air-conditioned reached 170 per cent of the annual average. The average over non-conditioned districts during the same two months was only 10 per cent. In a block of buildings containing theatres, hotels and restaurants all using air-conditioning the maximum per cent of the daily average was 250. Chicago is in the happy position that its major mains and pumping capacity seem sufficient for ten years more at this rate of growth. On the other hand, deficiencies of sewers will have to be made good, unless wasteful evaporative type cooling devices are installed in air-conditioning plant.

Earthing the Metal Sheathing of Electric Cables

A DIFFICULTY in connexion with electric supply when metal sheathing of electric wiring and apparatus is employed is how to connect this sheathing to earth in such a way that, in the event of it becoming electrified owing to a fault developing between the sheathing and a main, the faulty circuit may be disconnected at once and consequently the pressure between the sheathing and the earth cease to be dangerous. To secure this it is necessary that the sheathing be a continuous conductor of small resistance and that it is maintained in good electrical connexion with the earth. The Wiring Regulations of the Institution of Electrical Engineers stipulate that the electrical resistance of the metal sheathing or tubing must not exceed one ohm between any two points of its length. In practice this can easily be measured by testing. The connexion of this metal

sheathing to earth is more difficult to specify but in general it is stipulated that its resistance must not exceed one ohm. When it has this low resistance, the cut-out of the faulty main will act and so the sheathing and the metal in contact with it ceases to be dangerous. Where it is economically impracticable to obtain an earth having a resistance of not more than one ohm, earthing must be supplemented by an earth leakage 'trip-coil' so adjusted that it will operate at not more than 30 milliamperes. The resistance of an earth electrode depends very largely on the humidity and the character of the soil in which it is buried.

In many cases when the supply is taken from overhead mains and there is no water supply, compliance with the I.E.E. regulations is very difficult and practically impossible. In this case the neutral main of a four-wire system of supply gives an easy method of getting an approximate earth potential over the whole of the supply area. Where there are no parasitic currents from tramways, this system has many advantages. This system is used in some parts of Australia and New Zealand. The Electricity Commissioners and the Postmaster-General have given their special consent to its use in certain districts in Great Britain. When this system is adopted, no fuse must be inserted in any conductor connected with the neutral main. This leads to a simplification and consequent cheapening of electrical installation work. In Australia, the State Electricity Commission of Victoria has recently altered its wiring regulations. The provision of an automatic circuit breaker is made compulsory in all new installations. In addition, breakers have to be installed in all existing installations at the expense of the supply authority. It will be interesting to see how this works in practice.

The Enforcement of the Rules of the Road

SUGGESTIONS made by Dr. H. C. Dickinson, the chairman of the Highway Research Board of the U.S.A., are the subject of a recent report issued by Science Service. Traffic experts to-day are aiming at simplifying the traffic rules and reducing their number so far as possible. Dr. Dickinson has reduced them to four. The first is to keep to your own lane of traffic with only two thoughts in mind, namely, to watch the car ahead and to warn the car behind you whenever you do anything which changes your movement in your own traffic lane. Secondly, to realize that you have no right to cross or turn into another traffic lane. Thirdly, to give a clear signal, or indicate by the motion of your car, whenever you change from your own traffic lane. Finally, never exceed a speed at which the car cannot be stopped without interfering with other traffic in the lane. When an accident causes personal injury or damage to a car—other than fenders or bumpers—it should be obligatory for both parties to attend the action in court. In personal injury cases, the permits of all the drivers involved should be suspended pending the hearing, and the permit of innocent drivers, if any, could

then be restored. Dr. Dickinson makes the novel suggestion that when an accident has nearly occurred and has only been prevented by the quick-wittedness of one of the actors, regulations should be used which would enable 'enforcing' officers to issue 'tickets' to drivers endangering other drivers or pedestrians. The charge he suggests is that of 'creating a public danger', and the penalty a small fine or dismissal on probation. Repeated offences could be dealt with more severely. The object of the proposal is to make it very unpleasant for anyone who puts another person in jeopardy even although no harm results.

Zoological Types in India

THE series of "Indian Zoological Memoirs" has been enriched by an excellent monograph, illustrated by 85 text figures, on "Palæmon, the Indian River Prawn", by Dr. S. S. Patwardhan (Pp. xi+100. (Lucknow: Lucknow Publishing House, 1937.) 2 rupees). These monographs are intended to assist in the teaching of zoology in India by the selection of a number of readily obtainable types, which can be worked out fully by students in their own time and perhaps at their homes. A single animal studied closely in respect to its anatomy with the consequent consideration of the function of all its parts is bound to be of great help. To this is added, in the judicious selection of types here, the possibility for the student to study his forms in Nature. The illustrations are good black and white drawings in close proximity to the descriptions of the parts, and there are directions for the necessary dissections. If we are to make any suggestions, we would plead for a greater consideration of function, and references might be inserted freely, so that interested students may be induced to examine their types in a more intelligent manner. For example, in this prawn a consideration of the mode of action of the mouth appendages may be deemed essential to the study of their anatomy—and we find no references to the considerable bulk of recent work on this matter. Form and function are inseparable, and both are essential to the study of the living animal. For a young student, the author assumes a little too much, the monograph being more useful to his teacher.

Institution of Professional Civil Servants

THE eighteenth annual report of the Council of the Institution of Professional Civil Servants covers the year 1936 and refers to a large increase in membership, which was 50 per cent greater than in 1935; when the figure of 10,000 was reached for the first time. One of the outstanding achievements of the year was the successful prosecution of salary claims on behalf of architectural and civil engineering and mechanical and electrical drawing office staffs. The satisfactory settlements which were reached are attributed largely to the extensive research of the Committee, which proved that such staffs were underpaid in comparison with similar employees outside. The report again emphasizes the importance of the National Whitley Council to members of the Institution. The

Council has also been concerned with the completion of the application of the recommendations of the Carpenter report to scientific establishments, and in his presidential address at the annual meeting on April 29, Sir Richard Redmayne emphasized the necessity for the upgrading of the highest professional and scientific posts in the Civil Service, which, so far as remuneration is concerned, compare most unfavourably with posts carrying a similar responsibility outside the Service. A sub-committee is considering appropriate salaries for those professional posts outside the scope of arbitration with the view of making representations to the authorities. The Association is also dealing with the salaries of architects, engineers and surveyors in the Civil Service. Sir Richard criticized the Treasury for refusing to allow the reference to arbitration of the Institution's claim that women scientific officers should receive the same scales of pay as their male colleagues in the same grade, and stated that the Chancellor of the Exchequer had been asked to receive a deputation on this question.

Fruit Supplies in 1936

THE Intelligence Branch of the Imperial Economic Committee has issued a volume dealing with fruit supplies during 1936 (H.M. Stationery Office, pp. 106. 2s. 6d. net or 2s. 9d. post free). 55 per cent of the total import of fruit was of Empire origin. So high a proportion has never before been reached. There are, however, some very potent lessons for the home producer. The present report gives the convincing information that each apple tree yielded an average of 12.7 lb. of fruit in 1935, and 68.3 lb. in 1936. The "untimely and unusually severe frost" in May of 1935 is mentioned as the main cause of that season's low yield. It cannot be emphasized too strongly that the effects of frost are now largely within the control of the grower. The pioneer work of Mr. George Harrington, the investigations into general principles by various scientific workers, and the practical experiments by the technical staff of Messrs. Geo. Monro, Ltd., have made the practice of orchard heating a practical proposition without heavy finance. Total imports of raw fruit into the United Kingdom remain fairly steady around an average of nearly 28,000,000 cwt., and apple imports are not very variable around a mean of about 6,500,000 cwt. Imports of grapes, peaches, lemons, pineapples and plums from Empire sources were higher in 1936 than ever before, and more bananas were imported by Great Britain than in any previous year. Supplies of fruit from South Africa reached a new record. Totals for most fruit imports were, however, lighter than in 1935.

The Ross Institute

A MEETING of the Industrial Advisory Committee of the Ross Institute, which is now incorporated with the London School of Hygiene and Tropical Medicine, was held on May 28, at which the activities of the Institute were surveyed. Useful discussions also ensued upon the housing of African labour, the

risk of malaria when replanting rubber, the Indore process of disposal of night soil and town refuse and courses of instruction for laymen proceeding to the tropics. Information was also given of an investigation by Dr. Crowden at the School of Hygiene of experiments on air-conditioned cubicles for use in the tropics.

Fast Atlantic Crossing by Air

THE Empire flying-boat *Cambria* crossed the Atlantic on September 28 in the fastest time ever recorded. The distance of 2,000 miles from Newfoundland to Foynes, near Limerick, was covered in 10 hr. 36 min., giving an average speed of 190 miles an hour. According to the account in *The Times* of September 29, Captain G. J. Powell made tests of speed at various altitudes. During the first part of the flight he remained at 4,000–5,000 ft. and made speeds of 172.6–185 m.p.h. Later he climbed to 7,000 ft. and attained a speed of 195 m.p.h. Bad weather then forced him to 13,000 ft. when his speed fell to 167 m.p.h. Eventually, he reduced the height to 10,000 ft., where the most favourable wind for the easterly part of the journey was found.

The Night Sky in October

SUMMER Time ends on October 3 at 2^h U.T. The moon is new on October 4 at 12.0^h and full (the Hunter's Moon) on October 19 at 21.8^h. Conjunctions between the moon and the planets occur as follows: Venus on October 2 at 4^h; Mercury on October 3 at 6^h; Mars on October 11 at 18^h; Jupiter on October 12 at 17^h and Saturn on October 18 at 8^h. On October 29 at 17^h, Mars and Jupiter are in conjunction; the two planets passing within 1 $\frac{1}{2}^{\circ}$ of one another (heliocentric positions). On October 11 at 6^h, Venus is in conjunction with Neptune. On October 15, Uranus is near the sixth magnitude star α Arietis; the diameter of the planet is $3\frac{1}{4}''$. The satellites of Jupiter, which always offer an attractive field for observation, present a few special features this month. On October 5 at 2^h 24^m–27^m Satellite II will be partly eclipsed by Satellite I. On October 7 a similar eclipse of these two satellites takes place at 22^h 07^m–24^m, the magnitude of the eclipse being 0.4. On October 17, I is partially eclipsed by III at 3^h 27^m–36^m. Appulses between II and I occur on October 12^d 01.9^h and October 22^d 1.0^h, whilst a complete occultation of II by I will take place on October 25^d 17.9^m. On October 13, Jupiter will occult the seventh magnitude star *B.D.* $-22^{\circ} 5100 = C.D. 13939$, the emersion being visible in Great Britain at 18^h 34^m at position angle 276° from the north point of the planet's image ("B.A.A. Handbook, 1937", p. 19). The light variation of Algol (β Persei) may be observed about 1 $\frac{1}{2}$ hours before and after the following times: October 3^d 19.6^h; 18^d 03.7^h; 21^d 00.5^h and 23^d 21.3^h. The periodic comet, Enoke, which was re-discovered by Jeffers on September 3 at the Lick Observatory, passes from Triangulum to Andromeda during the month. The comet, which was of magnitude 18 at the time of discovery, is still very

faint, its anticipated magnitude at perihelion on December 27 being about 5.5. An ephemeris for this comet is given by Dr. A. C. D. Crommelin in "B.A.A. Handbook", p. 34; corrections to this ephemeris are given by L. E. Cunningham, using the positions obtained by Jeffers at re-discovery. The zodiacal light may be seen before dawn in the first part of the month when the moon is absent. In view of the present general high level of solar activity, the northern skies may also be scanned for the presence of auroral light.

Announcements

H.M. QUEEN MARY has once again shown the keen interest she takes in the higher education of women by promising to visit the Royal Holloway College (University of London) at Egham on October 12. H.R.H. Princess Alice is chairman of the governors of this women's College, which has about two hundred students, and she shows a highly practical interest in the College and in the careers of its students. It is worthy of mention that during the university year just closing a student of Royal Holloway College, Miss Gladys E. Muddle, gained the Sherbrooke Studentship and the Sir John William Lubbock Memorial Prize, open to all students of mathematics in the University of London.

SIR THOMAS HOLLAND, principal of the University of Edinburgh, and formerly director of the Geological Survey of India, has accepted the presidency of the Geographical Association for 1938.

THE Le Chatelier Memorial Lecture of the Chemical Society will be delivered on October 28 at 5.30 p.m. by Dr. O. H. Desch, superintendent of the Metallurgical Department, National Physical Laboratory.

THE Sex Education Society has issued a programme of seven lectures to be given at the Conway Hall, Red Lion Square, W.C.1, during the present session. The first will be delivered by the president, Dr. Norman Haire, at 8 p.m. on October 5. The full programme can be obtained from the Honorary Secretary, 27 Harley Street, W.1.

THE Annual Conference of Greenkeepers will be held at St. Ives Research Station, Bingley, Yorkshire, on October 19. During the morning, a tour of the Research Station will be made, and during the afternoon a series of short papers will be given. A course on scientific greenkeeping will be held on October 20-26. The course will include non-technical lectures by members of the staff of the Research Station, coupled with practical work and demonstrations on the experiment ground. Further information can be obtained from the Director, St. Ives Research Station, Bingley.

THE British Drug Houses, Ltd., Graham Street, London, N.1, have issued a new edition of their

booklet dealing with B.D.H. standard stains, and including also a full range of the various materials required by the microscopist; the booklet may be obtained free on application. Useful notes are appended upon the bacteriological, histological and pathological applications of the various stains and materials, most of which can be supplied in small quantities suited to the requirements of the individual worker.

DR. S. O. BLACKTIN writes to point out that an error occurs in the short article contributed by Dr. J. S. Owens to NATURE of August 21 upon his "Electrotor Smoke and Dust Meter". The article was based solely upon a paper by Dr. Blacktin in the *Journal of Industrial Hygiene and Toxicology*, and not upon an examination of the instrument itself. Referring to the insertion of a new record disk, the words were used "and the cap with its disk screwed into position". Dr. Blacktin points out that this was a misunderstanding of the statement made in his paper; for the record disk is *not* supported inside the cap of the instrument but on a table under it.

THE Academy of Sciences of Cuba has recently celebrated the seventy-fifth anniversary of its foundation.

A CHAIR of social medicine has recently been created in the University of Paris. Its incumbent will initiate fifth-year students into certain elements of preventive medicine such as sickness insurance.

DR. JOHN E. GORDON, field director of the International Health Division of the Rockefeller Foundation, New York, has been appointed professor of preventive medicine and epidemiology at Harvard University Medical School.

THE John and Mary R. Markle Foundation of New York has presented one hundred thousand dollars to the National Research Council for the support of research in endocrinology in the next three years. The fund will be administered by the Division of Medical Sciences.

As the result of years of agitation by social reformers, no marriage will be possible in the Argentine in future unless the bridegroom is able to present to the civil authorities a certificate that he is free from contagious diseases transmissible in wedlock. The law, which is to be enforced immediately, does not apply to women. Other clauses in the law provide for the compulsory hospitalization of refractory cases of contagious infection and the closing of houses of ill-fame.

ERRATUM. In the obituary notice of Prof. H. E. Armstrong in NATURE of July 24, on p. 140, col. 1, lines 17 and 18 from bottom, for "Sir George Grove" read "Sir William R. Grove".

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 590.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Constitution of Aurous Compounds: Gold Mirrors

THE volatile aurous compounds described by Dr. F. G. Mann and Dr. A. F. Wells¹ provide further examples of the fact that, in its aurous compounds, gold is always 2-covalent. Constitutionally analogous sulphur and nitrogen compounds are also known. It is significant that whenever gold is in solution in the aurous condition, the metal is always present in a complex ion. This is shown in the cases of such typical compounds as potassium aurocyanide, $\text{KAu}(\text{CN})_2$, and hydrobromoaurous acid, HAuBr_2 . Like the auric ion, the aurous ion appears to be incapable of existence, and some investigations² have shown that the probable constitutions of the aurous halides and of aurous cyanide are respectively:

Thus, even in its simplest compounds, aurous gold appears always to be 2-covalent, while auric gold is always 4-covalent and the four valencies are coplanar with the gold atom³.

The production of gold mirrors by the heat decomposition of gold compounds is, of course, not new. Faraday in 1856 showed that drops of "gold chloride" solution evaporated in watch glasses and heated over a spirit lamp produced films which exhibited by transmitted light the same colours as the gold-containing liquids (Chemistry Exhibit, 157, Science Museum). In 1930, brilliant mirrors or films of pure gold were produced by gently heating the volatile trivalent and 4-covalent gold compound, diethylgoldacetylacetonate⁴:

Some of the first pure gold films produced at ordinary temperatures by the process recently described⁵ can be seen in the gold exhibit in the South African Court of the Imperial Institute.

Structure of Organic Molecular Compounds

THREE general conceptions are current as to the nature of the valence forces responsible for the formation of organic molecular compounds, each of which may conceivably be true as the limiting case in certain classes of compound:

(a) The molecular compounds are merely lattice compounds, involving no genuine chemical bonding, but depending for their formation and composition upon considerations of packing. This probably applies to such compounds¹ as CHI_3 , 3S_8 .

(b) Combination occurs by the formation of true co-ordinate links, as in inorganic molecular compounds. This view has been developed, probably incorrectly, in connexion with the polynitrobenzene-hydrocarbon compounds².

(c) Union is effected by the forces of interaction between strongly polar groups and the highly anisotropic, polarizable aromatic systems³. The London forces thus involved are, in a sense, intermediate between van der Waals's attractions and true covalencies.

During the past few months, an X-ray examination has been made of the quinhydrone and related compounds, with the view of eliciting the evidence of crystal structure as to their constitution. A similar approach to the nitrobenzene-hydrocarbon compounds was made by Hertel⁴, without conclusive results. The full results of the present investigation will shortly be presented elsewhere, but the following morphotropic considerations appear to lead the problem nearer to a solution.

(1) The discrete existence of quinonoid and quinoloid units in the structure, necessitated by the revised quinhydrone structure of Palacios and Fox⁵, is confirmed.

(2) The identity of the a and b dimensions in ordinary quinhydrone and in α -naphthoquinone quinhydrone (see table) show that the quinone and quinol groupings lie essentially in the (001) plane, with the breadth of the molecules along c , as was advanced for quinhydrone⁶.

(3) For dimensional reasons, the quinone and quinol units can alternate only along the a and c directions, but not along b . The formation of quinhydrone by a species of infinite hydrogen bond polymerization⁷, which, from the orientation of the molecules, could only take place along b , is thereby excluded.

(4) In phenoquinone, $\text{C}_6\text{H}_4\text{O}_2 \cdot 2\text{C}_6\text{H}_5\text{OH}$, b and c are essentially unchanged, whereas a is exactly $3/2$ times the a dimension of quinhydrone. Clear evidence is thus afforded that the components alternate along a . In various p -substituted phenoquinones, a and c are also slightly modified (due to the bulk of the substituents and to the inclination of the molecules to (001)) while retaining the same essential characteristics.

(5) The relation of the remarkably stable compounds of chloranil and bromanil with hexamethyl benzene, etc.—for example, $C_6Br_4O_2.C_6(CH_3)_6$ —to the quinhydrones⁷ is confirmed. The same alternation of components along a is observed, with identical a spacing; this brings the planes of the bromanil and the hexamethylbenzene molecules practically into contact. In these compounds there can scarcely be any question either of hydrogen bonds or of the formation of co-ordinate links.

(6) The direction of maximum light absorption in the quinhydrones and both the maximum of light absorption and the slow vibrational direction in the even more strongly pleochroic bromanil-hexamethyl benzene compound coincide with a .

	a	b	c	β	n
Quinhydrone	7.70	6.04	21.8	90°	4
$C_6H_4O_2.C_6H_4(OH)_2$	7.70	6.16	27.4	Rhombic	4
$C_6Br_4O_2.C_6(CH_3)_6$	7.40	8.83	28.7	Rhombic	4
$C_6H_4O_2.2C_6H_5OH$	11.50	6.16	22.2	100°	4
$C_6H_4O_2.2CH_3C_6H_4OH$	11.83	6.2	24.6	97°	4
$C_6H_4O_2.2Br.C_6H_4OH$	12.16	6.16	24.3	96°	4
$C_6H_4O_2.2Cl.C_6H_4OH$	12.00	6.16	23.5	97°	4

Along this direction the aromatic molecules are stacked plane to plane at a perpendicular distance of the order of 3 Å. The trend of the evidence makes the conclusion inevitable that this represents also the direction of bonding, in which case the mechanism (c) is the most probable. The formation of hydrogen bonds in quinhydrone is not necessarily excluded, and their presence is now being sought by the elegant method of Robertson and Ubbelohde⁸.

Duality of the Coproporphyrins in Bovine Congenital Porphyrinuria

Of the four theoretically possible isomeric types of porphyrins, only those belonging to Series I and III have so far been encountered in Nature. Haemoglobin, bilirubin, cytochrome, etc., are Series III derivatives. Series III has thus come to be regarded as the normal or 'physiological' type. Excretion of excessive amounts of porphyrins belonging to Series III does, however, occur in certain pathological states including lead poisoning (Grotepass¹, Mertens², Fischer and Duesberg³), pigment cirrhosis of the liver (Dobriners⁴), hepatic tumours (Dobriners⁴) and after administration of salvarsan (Sohreus⁵). The uroporphyrin excreted in acute idiopathic porphyrinuria has been shown to be uroporphyrin III (Waldenström⁶, Mertens⁷), whilst Dobriners⁴ has detected the simultaneous presence of coproporphyrins I and III in the stool from one such case.

The pigments formed in excessive amount by congenital porphyrinurias were until recently thought to

belong exclusively to Series I, but Fischer and Hofmann^{8,9}, working with material from the human case 'Petty', and Rimington^{11,12} studying congenital porphyrinuria bovines, have shown that small quantities of uroporphyrin III accompany uroporphyrin I in this disease.

We have now been able to isolate coproporphyrin III from the urinary and faecal coproporphyrin mixture of the same bovines, thus extending the duality also to the coproporphyrins. Evidence strongly suggestive of the presence of coproporphyrin III in small amounts in the bile porphyrins of a previous bovine case had already been obtained chromatographically by Rimington¹¹, but the quantities available were insufficient to allow of crystallization.

In the present instance, the total coproporphyrin fraction (faeces or urine) group was esterified and the more soluble coproporphyrin III methyl ester extracted by stirring with cold methyl alcohol (compare Dobriners⁴; we are indebted to Dr. E. Mertens for privately suggesting this technique). After several repetitions of this procedure, the Series III ester was dissolved in a few drops of dioxane, a little methyl alcohol added and then sufficient water, drop by drop, to render the mixture slightly opalescent. On standing in the ice-chest, the porphyrin was deposited in micro-crystalline form, m.p. 138/172° (Fig. 1). Synthetic coproporphyrin III methyl ester (the gift of Prof. H. Fischer, whom we wish to thank), crystallized in the same way, had m.p. 140°. Mixed m.p. 138°. Spectrum of ester in ether: 625.3; 599.3; 587.5–566.7; 531.6; 498.7. Three different preparations were made.

Fig. 1.

COPROPORPHYRIN III FROM URINE: BOVINE CONGENITAL PORPHYRINURIA. $\times$ ABOUT 100.

The occurrence of Series III porphyrins together with those of Series I in congenital porphyrinuria may be traceable to a secondary toxic effect (Fischer and Hofmann¹⁰), but is equally readily explicable on the basis of the scheme put forward by Rimington^{11,12} picturing a catalysed synthetic mechanism in the hamatopoietic tissue.

We have also encountered another pigment in these urines which we believe to be a hitherto

undescribed porphyrin. The methyl ester crystallizes in rectangular or rhomboidal prisms, resembling protoporphyrin ester, has m.p. 233–38° and a spectrum closely similar to that of coproporphyrin. The quantity obtained is as yet insufficient for analysis.

Disintegration Processes by Cosmic Rays with the Simultaneous Emission of Several Heavy Particles

On photographic plates which had been exposed to cosmic radiation on the Hafelekarr (2,300 m. above sea-level) near Innsbruck for five months, we found, apart from the very long tracks (up to 1,200 cm. in length) which have been reported recently in a note in the Wiener Akademie-Berichte, evidence of several processes described below.

From a single point within the emulsion several tracks, some of them having a considerable length, take their departure. We observed four cases with three particles, four with four and 'stars' with six, seven, eight and nine particles, one of each kind.

The longest track corresponded to a range in air (15°, 760 mm. Hg) of 176 cm. The ionization produced by the particles is different in the different cases. Most of the tracks show much larger mean grain-distances than α -particles and slow protons.

In Fig. 1 a 'star' with eight tracks is reproduced. On account of the rather steep angles at which some of the particles cross the emulsion-layer (approximately 70 μ thick) it is not possible to have all the tracks of a 'star' in focus simultaneously. Fig. 2 shows a sketch of the same 'star'. Measurement of the tracks gives the results in the accompanying table.

Track	Length in cm. of air (15°, 760 mm.)	Number of grains	Position of the end of the track
A	30.0 "	113	Within the emulsion
B	11.0 "	15	" " "
C	44.0 "	71	Glass " "
D	6.2 "	11	" " "
E	7.0 "	23	" " "
F	1.2 "	5	Within the emulsion
G	13.6 "	67	Surface of the emulsion
H	23.9 "	58	Glass

Centre of the 'star' 25 μ under the surface of the emulsion.

We believe that the process in question is a disintegration of an atom in the emulsion (probably Ag or Br) by a cosmic ray. The striking feature

about it is the simultaneous emission of so many heavy particles with such long ranges, which excludes any confusion with 'stars' due to radioactive contamination. A similar configuration of tracks by chance is equally out of question. Brode and others¹

FIG. 1.

observed a single case of a disintegration with three heavy particles in a Wilson cloud chamber. The phenomenon which Wilkins believes was a shower of protons is perhaps a similar process, but he did not observe a centre².

FIG. 2.

THICK LINES INDICATE A COMPARATIVELY LARGE NUMBER OF GRAINS PER UNIT OF LENGTH OF THE TRACK. AN INTERRUPTED LINE MEANS THAT THE TRACK IS TOO LONG TO BE REPRODUCED ON THE SAME SCALE. THE ARROWS INDICATE THE DIRECTION FROM THE SURFACE OF THE EMULSION TO THE GLASS.

The total energy involved in the process cannot as yet be calculated as most of the particles do not end in the emulsion.

We hope to give further details before long in the Wiener Akademie-Berichte.

Polarization of the Solar Corona

DURING the eclipse of June 19, 1936, at the observation station near the village of Kalenoe on the banks of the Ural River (U.S.S.R.), an investigation of the polarization of the solar corona was carried out by the expedition from Abastumani Observatory. The observations were made under perfect atmospheric conditions. A polarigraph with a reflecting analyser was used. The polarization was studied in two regions of the spectrum, corresponding to photographic and visual rays. In each series three plates were obtained with planes of polarization making angles of 60° . This enabled us to determine the degree and the direction of polarization at each point. On the plates the zone from $10'$ to $40'$ from the limb was found to be suitable for accurate photometric measurements. The effect of polarization is obvious.

From the study of the distribution of the degree and direction of the polarization, we can draw the following preliminary conclusions:

(1) The degree of polarization is different for different regions of the spectrum.

(2) The change of the polarization with increasing distance from the moon's limb is different for different heliographic latitudes, and depends on the structure of the corona. At places with a sharp radial structure (in corona streams) the polarization changes little, while between the streams it diminishes with the distance from the moon's limb.

(3) The direction of the polarization, while remaining approximately radial close to the solar poles and between streams, undergoes a strong but regular perturbation in the streams themselves.

The distribution of the direction of polarization in the outer corona (considering it as a vector) shows a certain analogy to the field of force.

Anomalous Dielectric Constant of Artificial Ionosphere

SINCE the earliest experiments of Barton and Kilby¹ in 1913 on the dielectric properties of ionized air, there have been many attempts by investigators to record experimentally the depression of the dielectric constant of an artificial ionosphere (as the ionized air in a discharge tube may more properly be called) to a value less than unity. It has, however, been found by almost every investigator that the reduced value of the dielectric constant could be obtained only under very special experimental conditions such as low value of ionization in the experimental discharge tube or ultra-high frequency of the exciting wave; while, more often than not, the value of the dielectric constant recorded was greater than unity. This latter result is usually believed to be contradictory to the theory, and various explanations have been put forward to explain the apparent anomaly.

The purpose of this note is to show from a consideration of the ionospheric dispersion formula that the so-called anomaly is not an anomaly at all, since the formula itself yields values of the dielectric constant greater than, equal to, or less than unity, depending upon the experimental conditions of the discharge tube such as the degree of ionization, the

pressure (that is, collisional frequency) and the exciting wave frequency.

The complete dispersion formula is given by

$$\left(\mu - \frac{i\alpha}{p}\right)^2 = 1 + \frac{1}{\alpha + i\beta} \quad \dots (1)$$

Where $\alpha = -\frac{p^2 m}{4\pi N e^2}$ and $\beta = \frac{m p \nu}{4\pi N e^2}$.

The symbols have their usual significance.

Fig. 1.

Separating the real and the imaginary parts, we have²

$$2\mu^2 = \sqrt{1 + \frac{2\alpha + 1}{\alpha^2 + \beta^2}} + \frac{\alpha}{\alpha^2 + \beta^2} + 1 \quad \dots (2)$$

$$\frac{2\alpha^2 \kappa^2}{p^2} = \sqrt{1 + \frac{2\alpha + 1}{\alpha^2 + \beta^2}} - \frac{\alpha}{\alpha^2 + \beta^2} - 1 \quad \dots (3)$$

It is easily seen from expressions (2) and (3) that μ^2 is greater than, equal to, or less than, unity, according as

$$\frac{|\alpha|}{\alpha^2 + \beta^2} \begin{cases} < \\ > \end{cases} \frac{\alpha^2 \kappa^2}{p^2}$$

If $\alpha > \beta$, expression (2), reduces to

$$\mu^2 = 1 - \frac{4\pi N e^2}{m(p^2 + \nu^2)} \quad \dots (4)$$

The approximate formula (4), which apparently suggests that μ^2 cannot attain a value greater than unity, has been responsible for the widespread belief "that the theoretical expression for the dielectric constant of an ionized medium does not permit values greater than unity, whatever the ionic concentration may be". Calculation of values of μ^2 from the complete dispersion formula shows, however, that the theoretical expression for the dielectric constant does permit values both greater, and less than, unity.

Figs. 1 and 2 are plots of equation (2). In Fig. 1, the dielectric constant is plotted against the ionic density N , all other quantities remaining constant. It is seen that only within a limited range of N can values of μ^2 less than unity be recorded. If N is increased beyond this range, the value of the dielectric constant increases and becomes greater than unity.

Fig. 2 is drawn for values of ν , N and p as were obtained in an actual experiment by Mitra and Banerjee⁴. The broken line prolongation of the left-hand portion of the curve is obtained by using the approximate formula (4). Mitra and Banerjee had explained the upward swing of the curve to the right

by assuming the effect of conductivity in their experiment. It is now seen that the existence of this portion of the curve is implied in the complete dispersion formula (2). The expression under the square root contains terms which take into account the

Fig. 2.

effect of conductivity. The fact that the experimental curve of Mitra and Banerjee, though similar in nature to Fig. 2, does not agree closely with it, shows that the disposition of the experimental apparatus had possibly some influence.

Effect of Near Lightning Discharges on a Magnetometer

DURING two thunderstorms at the beginning of the present monsoon, the recorded curves of the Copenhagen declination magnetograph recently installed at Alibag showed some characteristic features which on examination appear to be due to the effect of the magnetic field of the lightning discharge currents on the magnetometer. The magnetograms are reproduced in Fig. 1. The variations occurred between 2 hr. and 4 hr. and between 18 hr. and 22 hr. I.S.T. The storm was most intense in the second of the two intervals at about 20 hr. The magnetometer needle experienced a number of sudden kinks, and the subsequent oscillations gradually died down in 2-3 minutes. The maximum first deflection was about 1.5 mm.

It is easy to make a rough estimate of the deflection of the magnetometer needle that may be expected due to the magnetic field of a near lightning discharge. For impulsive discharges the total duration of which is small compared with the periods of the magnetometer, the instrument will behave as a ballistic galvanometer, the relation between the discharge current, its

duration, the constants of the suspended needle and the field in which it is suspended being given by the usual formula:

$$\int i dt = q = \frac{HT}{\pi G} \sin \frac{\theta}{2} \left(1 + \frac{\lambda}{2}\right),$$

if the magnetic field due to the current is perpendicular to H . In the present instance, T was 3.95 sec. and H was $\frac{0.876}{4.9}$ gauss. The effective magnetic field was smaller in the ratio 1:4.9 because, in order to increase the sensitiveness of the magnetometer, the north pole of the needle had been made to face south by applying torsion to the suspending quartz fibre

Fig. 1.

RECORDS OF A D. LA COUR DECLINATION MAGNETOGRAPH OBTAINED ON MAY 12, 1937, AT ALIBAG, NEAR BOMBAY, SHOWING THE EFFECT OF NEAR LIGHTNING DISCHARGES. THE TIMES ARE IN HOURS (INDIAN STANDARD TIME).

in the manner recommended by Dr. D. La Cour. Now G , the field at the needle (supposed short) due to unit current in the discharge circuit is given by

$$G = \frac{l \sin \theta}{r^2},$$

where l is the length of the discharge current, r its distance and θ the angle between r and the discharge path. The direction of the field is perpendicular to the plane containing l and the centre of the needle. Assuming $\sin \theta = 1$, $l = 2$ km. and $r = 2$ km., then $G = 5 \times 10^{-4}$. A probable value for q is 20 coulombs (see C. T. R. Wilson's article on Atmospheric Electricity in the "Dictionary of Applied Physics"). From these data the deflection of the needle can be easily calculated. It comes out to be $1/4820$ radian when the lightning discharge is most favourably oriented. The corresponding deflection on the chart when the distance of the photographic paper from the mirror of the magnetometer is 165 cm. is $2 \times 165/4820$ cm. or 0.7 mm. The observed and expected deflections are of similar magnitudes.

Attempts are being made to design a simple magnetometer with a Helmholtz compensating coil for the purpose of measuring the discharges of individual lightning flashes.

Sensitization of the Skin of Mice to Light by Carcinogenic Agents

WHITE mice painted twice a week for three weeks with benzpyrene in benzene are found to be sensitized to light. The mouse is painted and exposed to direct sunlight for a half to one hour; during the exposure the skin of the painted area becomes red and markedly oedematous. There is no latent period to this reaction; within a few minutes of the exposure the mouse becomes ill at ease, scratches the painted region and tries to hide it from the sun. The next day, the area shows a definite dermatitis.

Unpainted white mice having the hair closely clipped over the same region showed no reaction after three hours' exposure or at any subsequent time; unpainted areas in the experimental mice gave no reaction, nor did mice painted with the solvent.

Exposures to infra-red radiations and to ultra-violet radiations did not give rise to these reactions. By dividing the visible spectrum into three with Kodak gelatine filters, it was found that only the blue-violet light was effective: this corresponds with the absorption spectrum of benzpyrene.

Similar reactions have been obtained with tar and with di-benzanthracene, but which part of the spectrum is responsible has not yet been ascertained.

Gonadotropic Activity of Amphibian Anterior Pituitary

PREVIOUS attempts, using infantile mice or rats as test animals, to demonstrate the presence of a gonadotropic substance in the anterior pituitary of frogs have been entirely negative¹. Since implantation of frog's pituitary into frogs causes ovulation, Zondek comes to the conclusion that the frog's pituitary contains a gonadotropic substance which is inactive in warm-blooded animals. The negative results obtained by Lipschutz and Paetz and Zondek were probably due to the fact that the amount of pituitary tissue implanted was too small. Adams and Tukey, however, injected saline suspensions of from 16 to 96 frogs' pituitaries into each infantile mouse and still obtained negative results.

In view of the interest of this work from the point of view of comparative endocrinology, similar experiments were performed using *Xenopus laevis*, the South African clawed frog, as donor. Littermate female white mice 19-22 days old were used as recipients. In each experimental series one or two animals received a subcutaneous implant of frog anterior pituitary tissue; two to four mice received control implants of one of the following frog organs: brain, kidney, muscle, spleen, liver, ovary; one to three animals served as normal untreated controls. 72 hours later the mice were examined for opening of the vagina. They were then killed and the ovaries and uteri removed. The ovaries were dissected away from their oviducts and capsules. Fat and loose connective tissue were carefully removed from the uteri. All organs were immediately weighed on a torsion balance.

Implantation of 3.5 mgm. of anterior pituitary caused opening of the vagina but had no effect on the weights of either ovaries or uterus. Implantation of 8-20 mgm. caused opening of the vagina in all but two of twelve animals, also an increase in the weight of the ovaries and a two- to fourfold increase in uterine weight. In two mice hemorrhagic follicles (*bluepunkts*) were present in both ovaries; the uteri

weighed 31.0 mgm. and 32.5 mgm. (controls, 8 mgm.) and the ovaries 4 mgm. and 5 mgm. (controls, 2 mgm.). In seven animals uterine weights of 17-23 mgm. were obtained. All control implants gave negative results. A few of the enlarged ovaries were sectioned and showed definite follicular growth.

The ovarian, uterine and vaginal responses obtained in these experiments provide definite evidence that the gonadotropic substance of amphibian anterior pituitary can activate the mammalian reproductive apparatus.

Vitamin P

ACCORDING to Bentsáth and Szent-Györgyi¹, their experiments on the influence of vitamin P on the course of development of experimental scurvy² have been repeated at their request in several laboratories with the result that their observations were partly corroborated and partly not confirmed. This, they assert, is due to the fact that vitamin P requires for its activity the presence of traces of ascorbic acid.

In view of the fact that I repeated the above work independently, it is of interest to compare my results³ with the above. I was unable to record any vitamin P activity with daily doses of 1 mgm. of either 'citrim', hesperidin or a mixture of hesperidin and eriodictyol. When, however, sub-optimal preventive doses (0.1 mgm. and 0.2 mgm. of L-ascorbic acid a day) were administered alone to the experimental animals, a clinical and pathological condition was produced which resembled that obtained by Szent-Györgyi and his collaborators after the administration of vitamin P. This condition has always been known to occur when antiscorbutic doses lower than the minimum prophylactic dose have been offered to guinea pigs on well-balanced scorbutic diets, including the Sherman - La Mer - Campbell diet, which Bentsáth, St. Ruzsnyák and Szent-Györgyi used in their original investigation.

According to Bentsáth and Szent-Györgyi's latest view¹, one is driven to the conclusion that the basal diet I used (bran, barley meal, middlings, fish meal, crushed oats and autoclaved milk) contained no traces of ascorbic acid, which is undoubtedly true, but contained the hypothetical vitamin P, whilst the Sherman - La Mer - Campbell diet as used by them contained traces of ascorbic acid, although this is not evident from their negative control experiment⁴, but no vitamin P; alternatively, the biological action observed by them was due to the contamination of their 'citrim', etc., with traces of ascorbic acid. The object of this note is to record the bearing of my results on the modified view of Szent-Györgyi and his collaborator, which was advanced since the appearance of my paper, in the hope that it will help in the solution of this elusive subject.

Meteorites: the Number of Pultusk Stones and the Spelling of "Widmanstätten Figures"

IN criticizing others in *NATURE* of September 18 (p. 504), Prof. F. A. Paneth lays himself open to criticism. His calculation of the number of Pultusk stones is a remarkable example of what can be done with mathematics when all the factors are not taken into account. In 1868, Krantz supplied for the British Museum collection Pultusk stones weighing 3,545, 845, 793, 256 (half a stone), 139½ gm., and twelve others weighing together 243 gm. Towards the end of such a series it is the common practice to weigh the smaller stones together in one lot; and evidently the 212 (not 210) stones with an aggregate weight of 1 kgm. formed the tail-end of Krantz's stock. In 1908, Krantz was still offering Pultusk stones weighing 565, 492, 382 gm., and numerous others of less than 100 gm. While it is perfectly true that the best museums strive to acquire and preserve the best specimens, it is scarcely a balanced argument to quote, to the exclusion of these, a small private collection in Moravia, in which fragments of all the meteorites represented amounted to only 2 kgm.

In the British Museum collection there are 72 Pultusk stones with a total weight of 18,188 gm., the largest 9,095 gm. and the smallest 6 gm. (that is, less than the average in the Moravian collection); 264 in the Paris collection weigh 31,387 gm.; 175 in Chicago 14,291 gm.; 62 in Bonn 19,742 gm.; and 41 in Vienna 15,843 gm. These 614 stones account for half the total weight recovered. Individual stones of more than 1 kgm. in different collections (in addition to those in the British Museum) are 9,521, 8,070, 7,938, 7,150, 3,770, 2,500, 1,702, 1,040 and 1,025 gm. While it is not at all impossible or improbable that as many as 100,000 stones fell in this shower, the facts now available do not supply data for this to be proved mathematically.

In my paper in the *Mineralogical Magazine* in 1933 I collected fourteen variations in the spelling of "Widmanstätten figures" in the literature dating from 1813. Since then I have collected a few more. In the best books of reference the name of the discoverer is given as Widmanstetter (or Bech-Widmanstetter). Prof. Paneth quotes the Austrian Biographical Lexicon, giving (from E. Cohen) the date and page, but not the volume (Theil 55), which suggests that he did not himself actually consult the original. Here the entry is under "Widmanstetter", and the same also in J. C. Poggendorff's "Biographisch-literarisches Handwörterbuch" (1898, vol. 3). In the British Museum "Catalogue of Printed Books" a later member of the family, writing between 1870 and 1896, is catalogued under "Beckh-Widmanstetter" (Leopold von), with a cross-reference from Widmanstetter.

Spiriform Morphology of some Lead Crystal Growths in Silica Gel

It has been well known since A. L. Simon's description of the phenomenon¹, that fern-like crystal growths of lead can be obtained in silicic acid gels containing lead acetate solution. Whereas Simon used zinc to promote the electrochemical liberation of metallic lead in the gel, the use of tin for the same

purpose leads to the formation of crystals of a strikingly different morphology and lustre.

Under conditions recently studied in detail, which are characteristically critical as regards the concentrations of the reactants (particularly the lead acetate) a spiriform type of growth has been observed, to which no previous reference can be found in the literature. These growths arise electrochemically in a way entirely different from those helical and spiral precipitates of lead iodide, lead chromate and calcium phosphate described in the published work of Hatschek and his pupils², neither do they resemble the silver chromate spiral precipitates described in Hedges's "Liesegang Phenomena", nor the spiral crystals of M. Copisarow³. These spiriform lead growths often take a form resembling somewhat a very deeply cut screw having a minute barrel diameter, and with a very serrated edge to the pitch; sometimes the growths are like a thin ribbon of lead, twisted into a spiriform strip. The accompanying photograph

Fig. 1.

(Fig. 1), for which I have to thank Mr. E. Rowell of the Kodak Research Laboratories, Harrow, reproduces a six by one inch test-tube containing two such spiriform specimens. Whilst a non-stereoscopic view of them cannot adequately indicate the full screw-like features, a cinematic record reveals on rotating the tube that the two spirals in it are respectively right- and left-handed. At the points where they touch the glass walls, the spirals flatten out into serrated strips and these curl strikingly in opposite senses.

In collaboration with Mr. A. King of the Chemistry Department of this College, with whom work on these phenomena is being continued, it has been found that those gels, which are 0.02 normal with respect to the lead acetate concentration, can be made to reproduce spiriform growths, whilst identical gels containing a slightly different concentration of lead will produce many other strikingly different growths; the use of metals other than zinc or tin will also promote further modifications in their morphology.

Judgment by Hypothesis

PROF. J. B. S. HALDANE (see *NATURE*, Sept. 4, p. 428), in comparing my attitude towards Prof. E. A. Milne's cosmology with that of Lysenko towards the Russian geneticists, draws an analogy which seems to me little short of fantastic. According to *NATURE* of August 21, Lysenko treats Darwin's words as dogmas by which to judge and condemn, without examination, the work of modern experimenters. I accused Prof. Milne of imitating the practice of the Aristotelians who treated Aristotle's

words as dogmas by which to judge and condemn, without examination, the work of their contemporary experimenters. If there is any analogy to be drawn, it is surely between Lyenko and the Aristotelians (ancient or modern).

However, I am less concerned with that than with the possible implication that I wish forcibly to restrict Prof. Milne's work. On the contrary, I would place freedom of thought and expression second only to complete dedication to truth (or truthfulness, for those who think they can dispense with the shorter word) in the list of essential conditions for research. While I wish with all my heart that Prof. Milne would stop inventing systems and telling us what God cannot do, and would return to those problems in astrophysics which he is so peculiarly gifted to solve, I would fight to the last ditch for his right to waste his talents if he so wishes. My complaint is that he does not satisfy the first condition. He deduces systems from pure fancy, but instead of consistently calling them products of the imagination and presenting them as works of art, he tacitly identifies them with the world of experience and calls them scientific. Mathematics, according to the phrase which has been repeated and disregarded *ad nauseam*, is a subject in which we do not know what we are talking about. If Prof. Milne would eliminate such words as time, nebula, universe . . . from his

papers, and substitute x , y , z throughout, I would no more seek to restrain his activities than I would those of the surrealists.

Tritium or Triterium?

I HOPE it is not too late to protest against the use of the name 'triterium' for the isotope of hydrogen of mass 3. The name appears in the very interesting article by Lord Rutherford in *NATURE* of p. 303, and has apparently been used elsewhere, to judge by the quotations in that article.

The word 'deuterium' is correctly formed from the Greek δευτερος (*deuteros*), 'second', but the Greek for 'third' is τρίτος (*tritos*), not *triteros*. The name which corresponds properly with 'deuterium' is clearly 'tritium', and this word is already in use; for example, papers dealing with this isotope are indexed under 'tritium', and not 'triterium', in the indexes to the British Chemical Abstracts for 1935 and 1936.

KENNETH C. BAILEY.

Points from Foregoing Letters

COMMENTING on a recent remark by Mann and Wells on the production of gold films by heat decomposition of volatile gold compounds, Prof. O. S. Gibson refers to previous experiments of the same type. Also, he points out that in aurous compounds gold is always 2-covalent and that aurous ions, like auric ions, are apparently incapable of existence.

A table with details of the structure of quinhydrone and related compounds, as determined by X-ray analysis, is given by Dr. J. S. Anderson. The position of the quinone and quinol groupings, the relation of compounds of chloranil and bromanil to hexamethylbenzene and other structural characteristics are discussed.

A photomicrograph of coproporphyrin III, obtained from a bovine suffering from congenital porphyrinuria, is submitted by Dr. C. Rimington and G. C. S. Roets, showing that, as in the case of the related uroporphyrins, compounds belonging to both isomeric types (series I and series III) occur in certain pathological states.

Long-range ionization tracks, starting from a common focus in the emulsion of a photographic plate which had been exposed to cosmic radiation for five months at an altitude of 2,300 m., are considered by M. Blau and H. Wambscher to have been produced by disintegration of an atom in the emulsion by a cosmic ray.

Photographs of the solar corona, taken during the total solar eclipse of 1936 by means of a polarigraph with reflecting analyser, show, according to K. G. Zakharin, that the degree of polarization varies in different parts of the corona and also with the wavelength, and that the direction of polarization undergoes a change in the 'streams'.

Prof. S. K. Mitra and K. K. Roy point out that the complete formula for ionospheric dispersion yields

values for the dielectric constant which are greater than, equal to or less than unity, depending on degree of ionization, pressure and the exciting wave-length. The use of a simplified approximate formula had wrongly led to the opinion that theoretical considerations preclude values greater than unity, but such values were found experimentally.

Some characteristic fluctuations noticed in the declination magnetograms obtained at Alibag, near Bombay, are explained by Dr. K. R. Ramanathan as being due to the magnetic field of near lightning discharges. He points out that the magnetometer behaves as the needle of a ballistic galvanometer for these impulsive discharges, and suggests that this may be made the basis of an instrument for measuring the discharges of individual lightning flashes.

Implantations of the anterior pituitary of the frog into immature female white mice are found by Dr. H. Zwarenstein to activate the reproductive apparatus (opening the vagina, increase in weight of ovaries and uterus, and follicular growth).

Dr. S. S. Zilva observed no vitamin P activity on administering a daily dose of either 'citrin', hesperidin or a mixture of hesperidin and eriodictyol to guinea pigs on a scorbutic diet. He obtained, however, a biological response similar to that observed by Prof. A. Szent-Györgyi on administering sub-optimal doses of ascorbic acid. The bearing of these observations on Benteath and Szent-Györgyi's latest view concerning the action of vitamin P is pointed out.

ERRATUM.—In the note in *NATURE* of September 18, p. 509, referring to Dr. A. L. Reimann's communication, the statement: "the linear rate of decay of the phosphorescence of zinc-blende" should read: "the linear rate of decay of the *inverse of the square root* ($p^{-1/2}$) of the phosphorescence of zinc-blende".

Research Items

Eastern Himalayan Blood-Groups

IN view of the high percentage of Group *AB* found among Tibetans at Gyantse, Miss Eileen W. E. Macfarlane has obtained samples from Tibetans, Nepalis and Lepchas (*Man*, No. 159, August). The Tibetans were hospital patients and others at Kalimpong, North Bengal. The subjects either called themselves Bhutias or were Bhutanese. There are Bhutias in Sikkim State, who resemble the Tibetans physically and wear similar dress and ornaments. The Bhutanese were nearly all from Ha, Bhutan, and also belong to the Tibetan race. The sample in all numbered fifty-six. The proportion of the blood-groups differs considerably from the blood-groups observed by Tennant at Gyantse. The percentage of *B* is of the same order, and considerably lower than in the neighbourhood of Nepal. The percentage of *O* is much higher and of *A* lower than at Gyantse, the latter possibly being due to inbreeding, while the high proportion of *AB* may be a result of the Chinese garrison stationed there from the beginning of the century until 1912. The proportions found at Kalimpong suggest either that blood-group relationships differ markedly in different parts of Tibet, or that conditions in Gyantse are exceptional. One eighth of the Bhutias belong to Group *B*, more than a third to Group *A*, and almost one half to Group *O*, *AB* being rare. The preponderance of *O*, the characteristic group among American Indians, recalls the fact that the physical resemblances and similarities of artistic design between Tibetans and American Indians, especially the Navajos, has been noted as striking. The nearest Mongoloid neighbours of Tibet in China and Nepal are fairly high in *B* and it is remarkable that the Tibetans have absorbed relatively little of this group. They have evidently been isolated from the main stream of Mongolian migration since very early times.

Early Chinese Bronzes

AMONG a number of early Chinese bronzes from the Eumorfopoulos Collection, now in the British Museum (Bloomsbury), which are figured and described in the *Brit. Mus. Quarterly*, 11, 3, by Mr. R. S. Jenyns, is the famous ram-handled *tsun* which belongs either to the Shang-Yin, or early Chou Dynasty. This piece should convince sceptics that the Chinese bronzes of the classic period are equal, if not superior, to those of any other civilization. It is modelled in the form of two rams standing back to back, and is supported on four legs represented by their forefeet. From between their heads rises the funnel, which forms the mouth. The body is covered with scales, which may, or may not, have been engraved after casting. The conquest of Shang-Yin by the Chou princes about 1100 B.C. does not seem to have altered the Shang-Yin style. This *tsun* shows only one of the four innovations regarded by Karlgren as making their appearance at that period. It must, therefore, be very closely related to the Shang-Yin bronzes. It is difficult to account for the sudden appearance of the Shang-Yin culture, which produced highly complicated and distinctive bronzes without apparent effort. The mastery of technique and the conventionalized motives argue a long process of

evolution, and their inscriptions are far from primitive. Yet there is an enormous hiatus of time to be accounted for between the neolithic pottery from Western Kansu and Honan and these highly sophisticated vessels. The immediate ancestors of these are lacking. The Hsia culture, in which bronze casting and early forms of bronze must have made their appearance, remains a mystery. Even if it be admitted that bronze casting was introduced from the West in its finished form immediately before the Shang-Yin, the existence in Shang-Yin of forms evidently of great antiquity, which betray no affinity to known Western forms, is difficult to explain, without admitting a long process of internal evolution. We are compelled to believe that Shang-Yin culture had its roots in a distant past, but why almost no traces of that past have survived is a puzzle for which archaeology has yet to supply a happy solution.

Passerine Birds of Ethiopia and Kenya

DURING the months of its sojourn in Africa in 1911 and 1912, the Frick Expedition collected about 5,200 birds, besides a number of eggs and nests, and copious field observations, all due to the energy and collecting ability of the late Dr. Edgar Alexander Mearns. The description of the passerine birds by Herbert Friedmann adds to the faunal knowledge of an area remarkable for the wide range of its conditions, from desert to tropical rain-forest, from a rainfall of 0-11 inches to 70-80 inches, and from sea-level to 15,000 feet (*U.S. Nat. Mus., Bull.* 153, 479; 1937). Among the general features described is the marked tendency of far more lowland birds to range high up the mountain slopes in Ethiopia (to an altitude of 7,000-8,000 feet) than reach to about half that altitude (4,500 feet) in more equatorial portions of the continent. The authors regard the birds of these regions as having been derived from the steppes of south-eastern Asia by way of Asia Minor and Arabia during Pliocene times. In the course of this extensive movement many birds moved southwards through the area, such as the ancestors of *Francolinus ophana*, *F. africanus*, *Streptopelia capicola*, *Lophoceros melanoleucus*; others remained and formed a centre in which new species developed, and from which westward migration probably contributed to the fauna of the western savannahs the ancestors of such forms as the ground hornbill (*Buceros abyssinicus*), the parakeet (*Psittacula krameri*), the roller (*Coracias abyssinicus*) and the chat (*Oenanthe bottae*).

Self-fertilization in Japanese Slugs

THAT a pulmonate mollusc may possess the power of laying fertile eggs when kept in strict isolation has been known since Oken's experiments on *Lymnaea auricularis* more than a century ago. A number of other species have since been shown to behave in similar manner. K. Ikeda (*J. Sci. Hiroshima University*, March 1937) has conducted extensive and carefully controlled investigations into this phenomenon in the slug, *Philomysus bilineatus*. The young hatched in spring do not become mature until autumn, so need not be isolated until then; they mate in autumn but the eggs are not laid until after awaking

from hibernation in spring. The discovery of albino forms allowed a certain amount of genetical analysis. The fertility of the egg results from self-fertilization and not from parthenogenesis, and the power of self-fertility does not diminish with age. The individual spermatozoa descend the genital duct to attain fertilizing power in the receptaculum seminis, and the varying degrees of self-fertility exhibited by different species possibly result from differences in the ability of the spermatozoa to migrate through the duct.

Larvæ of Indian Coleoptera

IN *Indian Forest Records*, 11, No. 9, Mr. J. C. M. Gardner, of the Forest Research Institute, Dehra Dun, continues his series of articles on the immature stages of Indian Coleoptera. The present contribution deals with various Carabids, or ground beetles, and includes descriptions of the larvæ of species belonging to eighteen genera of these insects. As a number of these genera are European, and the structural characters of their larvæ are figured, the paper is of interest to workers other than those studying the Indian fauna. Very little has been published previously on larvæ of the Indian members of the family, and the present article, it is hoped, will be followed by others of a like character.

Aquatic and Marsh Plants of India and Burma

MR. K. P. BISWAS described some aquatic and marsh plants of India and Burma in a paper read before Section K (Botany) at the meeting of the British Association on September 7. India and Burma contain an enormous stock of aquatic and marsh plants in their many stationary and flowing waters. The hill streams in the Himalayas have their beds often covered with *Batrachospermum* and *Sirodotia* sp. The coastline, both the Malabar and the Coromandal, harbour large quantities of different species of marine algae. But there is still a vast field for the investigation of the marine flora of the coastline of India and Burma. The Andaman Islands, the Mergui Archipelago have also a rich vegetation of marine algae, chiefly composed of *Caulerpa*, *Sargassum* and *Halimeda*. The estuarine areas are marked by dense mangrove vegetation exposed to tidal action. On the west coast *Ceriops Roxburghiana*, *Avicinnia alba* are predominant. In the east, *A. officinalis*, *A. alba*, *Bruguiera gymnorhiza*, *Rhizophora mucronata*, *Acanthus ilicifolius*, *Agave majus*, *Ceriops Roxburghiana* are dominant species. In the Sundribun down to Mergui Archipelago and farther south the two palms, *Phœnix paludosa* and *Nipa fruticans* form quite a striking feature along the shore and deltaic areas. The larger rivers do not as a rule support much aquatic vegetation; but during hot months some portions of the beds of the rivers partially dry up, forming shallow pools separated from the main body of water. These pools form good culture beds of algae. Stationary water in the form of natural or artificial lakes, jhils, bils, tanks, pools, puddles and swampy areas (ricefield swamps) occupy a considerable area of the lower plains of the two countries. These, due to favourable edaphic and climatic conditions, are full of aquatic and marsh vegetation. In this mass of crowded vegetation, four zones can be distinguished: (1) the bottom layer, which may be called the zone of the vital layer; (2) the zone of rooted aquatics; (3) the zone of suspended vegetation, and (4) the zone of surface vegetation.

The inland brackish water plants are interesting, too. Such plants are often found in the plains of the cities near the sea, such as Bombay, Calcutta and Madras. The salt lakes of Calcutta retain a mixture of salt-water and freshwater vegetation in their swamps.

Polyporaceous Fungi

THE behaviour of nuclei in the developing basidium of the higher fungi has only been studied intensively during comparatively recent years. It has been generally established for one or two agaricaceous fungi that two nuclei fuse in the young basidium; the fusion nucleus divides, first by reduction division, and later by ordinary mitosis, to form the basidiospores. Dr. S. R. Bose adds welcome confirmation to this view, by showing that the Polyporaceæ possess a similar mechanism (*J. Ind. Bot. Soc.*, 16, No. 3, 119-128; 1937). Eleven species of Polyporaceæ have been studied, and results are given in detail for each species. Basidia are very small in the pore-bearing fungi, but a sufficient number of stages has been found to establish similarity of behaviour with other previously described Basidiomycetes. The mechanism of nuclear division is essentially similar to that of higher plants, though the chromosomes are too small to be counted satisfactorily. Dr. Bose has recently published a paper on "Polyporaceæ from Lokra Hills (Assam)" (*Ann. Mycologici*, 35, No. 2, 1937), in which he describes a number of species from an elevation of 5,000-10,000 feet. Many cosmopolitan fungi are included, and the accounts show that several polypores of temperate Europe and North America are found at this elevation in Assam, but are absent from the plains of Bengal. *Fomes fomentarius* is a typical example of such distribution.

A Dune Drainage System

MR. V. J. CHAPMAN has described an investigation made in 1933 to determine the nature of the water-table movements in the salt marshes of Scolt Head Island on the Norfolk coast (*Mem. and Proc. Manchester Lit. and Phil. Soc.*, Session 1936-37). The area selected was especially convenient for the experiment as there is a small artificial pond near the centre, and it was the rise and fall of the water in this pond that prompted the investigation. The information obtained showed that while the diurnal tidal movements did not sensibly affect the level of the pond, it rose appreciably and rapidly about 48 hours after every maximum spring tide which reached a height of 27 ft. above Hull datum and then fell slowly. Particulars were also obtained showing the direction of the drainage flow. These water-table movements have a profound bearing on the plants which grow in the dunes and which, in order to tap the supply of fresh water known to float on top of the salt water, develop long roots. Without these periodic fluctuations of the water-table many of the dune plants would not be able to exist in summer when their need of water is great. To this extent, it is suggested, the flora of dune hollows may be associated with and dependent upon the subterranean water supply, assisted possibly by some capillary action in the sand. The conclusions reached as a result of this short investigation agree with those of earlier research carried out at Blakeney Point, and are therefore thought to be representative of the conditions in dunes in this part of Norfolk. These are that no flow takes place until the high spring tide reaches a

certain minimum level, that then a rapid rise takes place after a lag of 48 hours and that, except at these very high tides, the water drains out along the line of least resistance following a shingle path to the shore.

Meteorological Connexions between Greenland and Europe

At a meeting of the Royal Meteorological Society held on June 16, Dr. F. Loewe read a paper entitled "A Period of Warm Winters in Western Greenland and the Temperature See-Saw between Western Greenland and Central Europe". He referred to the studies of Grosse, Wagner and Scherhag on the marked change that has taken place in the climate of Greenland since about the beginning of the present century in the direction of milder winters and slightly warmer summers, resulting in a decrease of the mean annual range and therefore in a more oceanic climate. For example, the average difference between the extreme seasons from 1923-34 at Jakobshavn was 19.5°C . compared with 24°C . for the period 1876-1934. A striking individual instance of winter warmth is that of the period January-March 1929 when Jakobshavn temperature was 12.7°C . above the 1876-1935 mean, and the coldness of the same period in northern Germany (it was the coldest winter probably since 1830 and certainly since 1838) illustrates the see-saw of temperature with which the second part of the paper deals. This see-saw effect was pointed out by Hann so long ago as 1890, who observed that in the winter months the anomalies of temperature at Vienna and Jakobshavn were of opposite sign, but Dr. Loewe finds that the contrast with west Greenland is greater for the region around the Baltic than for Vienna. He gives a table of temperature anomalies for the nine warmest and nine coldest winters at each of the three stations, Jakobshavn, Breslau and Uppsala, for the period 1876-1930, and the corresponding anomalies at the other two stations, which illustrates the effect very well. The 54 sets of figures contain only two years, 1916 and 1930, with big simultaneous positive anomalies on both sides of the North Atlantic. The main reason for the see-saw is clearly to be found in pressure conditions between Greenland and Norway, high pressure tending to bring polar air down to the Baltic and tropical air up to West Greenland, and low pressure in the same area a reversed exchange of tropical and polar air.

Fluoroform

A MINUTE amount of a substance which was probably fluoroform, CHF_3 , was obtained by Mehlans in 1894 by the interaction of iodoform and silver fluoride. It was prepared in a pure state by Ruff in 1936 by the interaction of iodoform with a mixture of mercurous and calcium fluorides. A. L. Henne (*J. Amer. Chem. Soc.*, **59**, 1200; 1937) has now described a method suitable for larger scale preparation. In this, bromoform is heated in a closed steel vessel with antimony fluoride (SbF_5) and some bromine. This gives the substance CHF_3Br , b.p. -14.5° . This is carefully purified and is then treated with mercuric fluoride in a similar apparatus, with special temperature control. The gaseous CHF_3 evolved is collected over water, condensed by liquid air and distilled through a condenser cooled at -80° ; CHF_3 (b.p. -88.2°) passes on. The substance is very inert chemically and physiologically. Alkalis and acids are unaffected by it, bromine does not react in

bright sunlight, but fluorine reacts vigorously with formation of CF_4 and HF . The atomic distance between the carbon and fluorine atoms (as measured by L. O. Brockway) is 1.35 Å. By the action of chlorine in bright sunlight, hydrogen is replaced and CClF_3 formed. This boils at -81.1° and, as CHF_3 , boils at -82.2° , it is seen that in these compounds a replacement of hydrogen by chlorine has caused a rise in boiling point of only 1° .

Effect of Pressure on Phosphors

It is well known that powdering a phosphor results in a diminution of the intensity of the light emitted, but that uniform pressure produces no change in the intensity. Smekal's theory gives a satisfactory explanation of the effect of powdering. A comprehensive investigation of the effect has now been made (N. Riehl and H. Ortmann, *Ann. Physik.*, [v], **29**, 556; 1937). It was first shown that powdering does not affect the specific gravity of either zinc sulphide or alkaline earth sulphide phosphors. An attempt was then made to determine the percentage of active centres which are rendered inactive by the effect of pressure, the work being confined to the zinc, calcium and strontium sulphide phosphors. The opinion is expressed that the absolute effect of pressure was widely overstated in the earlier work, the reason being that the transparency of the phosphorescent layer was greatly decreased by powdering. For a medium-powdered phosphor it is estimated that the effect is only to reduce the intensity of the emission by 10 per cent, and this is near the limit of accuracy of the experiment. For an extremely finely powdered phosphor the diminution was only about 36 per cent. A rough estimation of the number of centres which come to the surface on account of the powdering agrees well with the experimentally determined decrease in intensity.

Spectrum of Nova Herculis

A LARGE number of papers on the spectrum of Nova Herculis has appeared since the discovery of this star in 1934, but one of the most complete and detailed accounts is that published recently by D. B. McLaughlin (*Pub. Obs. of Univ. of Michigan*, **6**, No. 12). The method of presenting the observational material is worthy of note, since the author discards "that most deadly of methods of discussion: the day-to-day journal of observations" and divides the history of the nova into typical stages, with separate treatment of each stage as a unit. Day-to-day changes of more important characters are, however, to be found in the numerous tables or diagrams. Wave-lengths, identifications, intensities and radial velocities are given for each group of absorption or emission lines which occurred in the various stages considered, together with critical accounts of the main features typifying each stage. It is impossible to summarize the many interesting results obtained, but special mention might be made of the anomalous behaviour of the Mg II line at 4481 Å., which showed radial velocity changes at variance with those of all the other absorption lines. It is described as "one of the most remarkable enigmas of the Nova spectrum". Some correlations are found between spectral changes and luminosity, and a tentative hypothesis is offered in which an interesting variant of the expanding shells hypothesis appears to give a satisfactory physical interpretation of the principal features observed.

The Relation of Growth Substances to Horticultural Practice*

By Dr. M. A. H. Tincker, Royal Horticultural Society, Wisley

MUCH of our recent knowledge of plant hormones we owe to the Utrecht botanists, whose investigations led to the recognition of the nature and function of these substances. Earlier experiments carried out with seedling oats showed that the shoot apex produced substances capable of regulating growth. When cut off and placed on gelatin, quantities exuded from the tips of the active substances proportional to the number of seedlings used for a fixed period of exudation. These substances could be transferred to other seedlings. A wide search was made for a ready source of these compounds, found to be present in small quantity in grain, pollen and leaves. Higher concentrations are available in urine.

At the Leicester meeting of the British Association Prof. F. Kogl described the isolation and chemical recognition of auxin *a* and *b*. Their structure is complicated; but with these two compounds a third active compound, hetero-auxin, was found. It is a simpler chemical, β -indolyl acetic acid, previously well known to chemists.

Small quantities (5 mgm.) of indolyl acetic acid when applied in lanolin, a convenient solvent, to the young stems of tomato plants growing vigorously, cause within 24 hours twisting and bending of the petioles and stems, as unequal growth takes place on the two sides. This is a quick ready means of testing closely related and other chemicals. In a few days, roots appear from the stem, root initials also develop inside, clearly seen by cutting the stem longitudinally. Similarly, the production of roots may be induced in severed portions of plants, and this is the practical point, for vegetative reproduction is thus facilitated.

The paste method has been largely superseded by dilute solutions. Herbaceous or woody cuttings are taken with expanded leaves, their basal ends placed in the solution to a depth of an inch; owing to the loss of water in transpiration from the leaves, sufficient solution is taken up to induce subsequent root production when the cuttings are placed, after washing in water, in sand in propagating frames.

The list of active chemicals includes the related indolyl butyric and indolyl propionic acids. The organic salts or esters of these acids are active, so are some of their metallic salts such as sodium indolyl-acetate. Scatole has recently been proved active. Alpha and beta naphthalene acetic acid are very highly active, phenyl acetic and anthracene acetic acid are less active.

Although fairly closely related, iso-indolinone is inactive. The substitution of sulphur for the nitrogen and hydrogen group in indolyl acetic acid very greatly reduces the activity. Although closely related to indolyl propionic acid, tryptophan is inactive; it may be a stage in the formation of the growth substance in Nature.

The treatment causes: (a) more cuttings to form roots; (b) more roots to be formed on each cutting;

(c) the active process (including *a* and *b*) to be accelerated.

Amongst herbaceous plants, cuttings of lupins, delphiniums, pelargoniums, violas and alpine phlox have shown accelerated rooting by treatment with pastes in lanolin and with very weak solutions. There is a tendency to damage delicate tissue by the use of solutions of too high a concentration; 1 part in 30,000 or 40,000 parts of water is recommended for such cuttings.

With holly, taken at the end of June and treated with indolyl acetic acid, 1 part in 10,000 of water for 24 hours, half the cuttings rooted in 6 weeks whilst none of the controls, placed in water for 24 hours, rooted in this time. With *Viburnum Carlesii*, cuttings taken at the end of July and treated with alpha naphthalene acetic and others with indolyl acetic, 1 part in 10,000 of water for 24 hours, rooting took place rapidly. In ten days, the active growth taking place inside the stem split the outer layers. Cuttings of *Oeanothus dentatus* taken in late November produced roots in January, and *Myrtus communis* cuttings taken in January rooted in a month. Stimulation may occur at a season of normal quiescence.

Species and varieties of heather (*Erica*) responded quickly to alpha naphthalene acetic acid, *Pieris formosa* taken in late August and *Gaultheria procumbens* have given favourable results. With *Rhododendron rubiginosum*, 85 per cent of the cuttings treated in alpha naphthalene acetic acid and indolyl acetic acid, 1 in 20,000 for 48 hours, rooted in three months, whilst only 5 per cent of the controls form roots. Other plants tested include species of *Buddleia*, *Camellia*, *Deutzia*, *Escallonia*, *Hydrangea*, *Pernettya*, all of which showed favourable results by these methods. Even with the more recalcitrant genera and species some encouraging results have already been obtained. Further results are reported in tests made by horticultural and chemical firms, and at other research stations and laboratories. These greatly extend the list of species in which root formation has been accelerated. Certain species may yet prove quite unresponsive but the indications are to the contrary, provided the time of year and concentration of solution can be correctly selected.

The concentrations are surprisingly low, for frequently 1 in 40,000 of water is effective. It appears from certain *ad hoc* tests that there is a critical concentration below which little or no activity is induced. Twice the length of time for uptake from a solution half as concentrated may not be so effective as a stronger solution used for the given time.

Pouring solution on to the sand before inserting cuttings is not recommended, as bacteria interfere. Freshly made solutions should be used as moulds and bacteria may contaminate them if kept. Since the solutions are not stable in light, storage in coloured and opaque vessels at higher concentration is recommended.

The success obtained has been quickly appreciated

* Substance of a lecture to Section K (Botany) of the British Association, delivered at Nottingham on September 3.

by chemical manufacturers and by horticulturalists. There are now a number of solutions readily available on the market in many countries.

Thus it is seen that investigations, primarily of botanical interest, dealing with fundamental problems

of plant development, have quickly led to results of much interest and value to the practical man; showing once more the relationship of science and its discoveries to everyday life, to industry and to recreational pursuits.

The Teaching of Geology in Schools

JUST over two years ago, at the Norwich meeting of the British Association, Section C (Geology) appointed a committee to report on questions affecting the teaching of geology in schools. A short report was presented at the 1936 meeting of the Association, and, at the suggestion of members of Section L (Education), an extended report giving detailed proposals was prepared for the Nottingham meeting. These reports were discussed in a joint meeting of Sections C and L, at which Mr. H. G. Wells presided, on September 7.

The views of the geologists were explained by Prof. A. E. Trueman, who opened the discussion, Prof. G. Hickling, Prof. W. W. Watts, Prof. L. J. Wills, Sir Lewis Fermor and Prof. P. G. H. Boswell. It was pointed out that, while geology has never figured very prominently in school curricula, many pupils were formerly introduced to it, for example, on field excursions, by teachers who had received some training in the subject, but that few intending teachers at present are encouraged to include it in their university or college courses. While appreciating something of the difficulties of the overcrowded curriculum, it was felt that geology should be more widely included in school courses. The Committee did not press its claims in competition with any other subject; in general, while it wished to secure the inclusion of some outlines of geological knowledge in all science courses in secondary schools (for example, as a part of schemes of 'general science'), it only asked, in addition, that geology should be included as an optional subject at more advanced stages. The inclusion of some geology in the scheme of informative education outlined by Mr. Wells in his address to the Education Section was noted with keen satisfaction.

Both the cultural and utilitarian aspects of geology were emphasized. It is one of the richest of cultures, stimulating a broader interest in the outside world and increasing the appreciation of scenery. On the other hand, it is an eminently useful science with numerous and obvious applications in mining, engineering and agriculture. It was suggested that geology should form an essential part of the school curriculum in mining and industrial areas, partly on account of its economic importance, partly for the wider interest it would give to later life.

The syllabuses proposed by the Committee are intended only as suggestions, and great elasticity of treatment appears to be desirable in the case of geology even more than in other sciences, the bias and the arrangement of the various topics depending largely on the location of the school.

In the senior elementary schools there is more opportunity for variety of treatment, and a rather practical bias is suggested. Dr. W. K. Spencer described some of the work carried out in such schools.

The lack of any courses in geology in most schools was held responsible for the present dearth of trained

geologists; Prof. Hickling and Prof. Watts pointed out that while the supply is thus restricted the demand for geologists is increasing. It was emphasized that there are attractive careers in this field for a number of men of ability and good physique.

Two teachers who took part in the discussion expressed rather different points of view. First, Mr. James Davies, one of the few teachers who are actually teaching geology in secondary schools, indicated the nature of his courses. In pleading for a wider adoption of geology he spoke of the attractiveness of the subject and said that there is nothing more inspiring than leading a party of young people over hill and dale (his school is in South Wales). As an example of the chance of a beginner in geology making new discoveries, he mentioned the first recognition of a marine band in the Coal Measures by one of his pupils. In his school, both geology and geography appear in the curriculum. On the other hand, Mr. V. C. Spary, speaking as a teacher of geography, expressed fears that the introduction of geology into the time-table could only mean the displacement of geography. He agreed, however, that a well-balanced course of geography must include many lessons of a geological nature, for "geography teachers must borrow a great deal", and he thought it a great advantage for teachers of that subject to have some geological training.

Mr. Wells agreed with Mr. Spary that the teaching of geology as a specific subject is not highly desirable until an advanced stage in education is reached, but thought that reference would nevertheless be made at earlier stages to the geological record when teaching biology, and to physiography in teaching geography. He went on to inquire what constitutes geological training when the biological and physio-graphical sides are taken away. In reply to these questions it was insisted that palaeontology and physiography are branches of geology, and while it may be convenient to treat them in relation to other subjects in the curriculum, it is desirable that the pupils should know that they are then learning geology. Anxious as they are to see their subject taught in schools, geologists would much prefer to have it taught under its own name.

In the course of the discussion, there was no real criticism of the view that geology should be taught in schools; there was, however, this difference of opinion as to whether it should appear as a separate subject except at more advanced stages (for example, at the Higher School Certificate stage). The inclusion of the subject as a part of a course in 'general science' would possibly be the most satisfactory solution in many schools, up to the stage of the School Certificate, as the Committee had recommended.

In connexion with the discussion, Prof. H. H. Swinnerton arranged an interesting exhibit to show a course of simple experimental work in geology suitable for schools.

Fossil Man in Minnesota*

IT is probable that there is no skeleton of ancient man of which the circumstances and conditions of discovery have been more carefully documented than that of the skeleton found in the ancient glacial lake deposits, now known as "Lake Pelican", beneath Minnesota Highway No. 30, near Pelican Rapids, on June 18, 1931 (see NATURE, Feb. 27, p. 385). Prof. A. E. Jenks, in his detailed account of the skeleton, has been careful to secure statements from all who were concerned in the discovery of this skeleton; and the facts were further checked by a re-excavation on the site, in which the circumstances received further confirmation by the occurrence of more fragments of the skeleton.

The skeleton was unearthed at a depth of some twelve feet in the course of repairs to a recently made road, when a mechanical excavator was noticed by the workmen to have crushed a clam shell. A closer examination revealed the existence of a skeleton, which on removal proved to be virtually complete. One tooth, lost after discovery, is missing, as are the nasal and some of the smaller bones, such as those of one hand and the feet.

Minnesota is the centre of an area of some thousand miles in extent which, as a zone of terminal moraines and a 'driftless area,' would have been peculiarly favourable for the existence of glacial man. The ancient glacial lake system to which belong the deposits in which the skeletal remains were found is of late Pleistocene date. This area would have been readily accessible to early man entering America by either the Arctic coast or the Yukon valley, and thence coming south-eastward along the Mackenzie River and on the east of the Rocky Mountains, and thereafter in a generally eastward direction along the Missouri River. Hence access could readily be gained to the various centres in America in which forms of aboriginal culture developed later.

The skeleton as a whole, as already mentioned, is very complete. It is that of a sub-adult female of about fifteen years. The bones are mineralized, and little affected by the silt in which they lay. There can be no question of a modern burial, and the supposition is that the young woman was drowned in glacial Lake Pelican about half a mile from the foot of the glacier, possibly having fallen through the ice.

The characteristics of the cranium are not distinctively primitive in type, except in the backward extension of the skull and the 'houseboat' shape, which is also characteristic of the Australian and Eskimo. The cephalic index, 77.09, distinctly mesocephalic, and therefore higher than in the Mousterian and Aurignacian types, and the head-height indices are not very distinctive of race, falling in the median categories, which may be found in all the great groupings of mankind. The cranial vault shows a number of primitive characters, of which the more noteworthy are the prominent glabella, the absolutely and relatively long temporal margin of the parietal bone, the low index of the squamous portion of the temporal bone, the high position of theinion above

the Frankfort plane, and the flatness of the nuchal area. A number of unique or unusual features are shown, such as the U-shaped grooves of the occiput and the columnar form of the bases of the pterygoid processes.

The face as a whole shows an important primitive characteristic in the marked alveolar prognathism combined with mid-facial orthognathism. In this it most closely resembles neanthropic palaeolithic Europeans. In other measurements and indices the resemblance is nearest to the Mongoloid and White groups. As contrasting with certain Amerindian groups, it is both higher and narrower; yet it is within the group means of Algonkians, and in breadth within the range of the Siouan group. In orbital index the specimen falls with the Mongoloids; while the interorbital breadth and index are Mongoloid. The nasal index is closest to the White, yet certain of the Mongoloid groups have similar indices. The forward thrust of the maxilla is Mongoloid; while the mandibular index is closer to that of the Australians than of any other living race.

The teeth exhibit important primitive characters. They are absolutely large in every respect. In the relative length of the lower molars the third is the greatest, which gives them a unique formula. The cusps of none of the molars show any reduction in number, and they retain the primitive crown patterns. The shovel-shaped upper incisors, though characteristic of the modern Mongoloids, seem to be a primitive character.

The stature as computed from the long bones is 1,582 mm. (Manouvrier) or 1,540 mm. (Pearson). This, on Manouvrier's method, is slightly above the average for females generally, which is 1,530-1,539 (Martin). The figure is above the Mongoloid average, which is generally lower than European and Negro.

Artefacts were found with the remains. The clam shell crushed by the grader has been identified as *Lampsilis siliquoides*. As this lay above the frontal bone it may have been part of the headdress. An antler dagger, broken at the time of discovery, lay to the right of the right humerus, and has been identified as part of the time on the main beam of an elk antler. It is 196 mm. in length and had been fashioned by a coarse cutting implement. Its butt end is perforated. A conch shell pendant was found among the ribs and vertebrae in the abdominal area. At the second re-digging of the site sixty fragments of turtle carapace were recovered, also fragments of antler, metatarsal of a loon, toe bones of a bird's foot, a wolf's tooth, and the calcaneum of a rodent. The whole possibly was a 'medicine' outfit.

The general deductions are that the skeleton named 'Minnesota man' has been found geologically documented in undisturbed sediment of late Pleistocene origin in the area immediately east of the Big Stone Moraine of the Wisconsin glacier; and that the measured and observed morphological characters of this skeleton proclaim it to be a primitive *Homo sapiens* of an early type of evolving Mongoloid, already prophetically suggesting American aborigines, especially the Eskimo, more than the present Asian Mongoloids, and living in west central Minnesota about twenty thousand years ago in late Pleistocene times.

* Pleistocene Man in Minnesota: a Fossil *Homo Sapiens*. By Dr. Albert Ernest Jenks. With a Chapter on the Pleistocene Geology of the Prairie Lake Region, by Dr. George A. Thiel. Pp. xiv+197. (Minneapolis, Minn.: University of Minnesota Press; London: Oxford University Press, 1936.) 34s. net.

Naval Architecture and Engineering

A SAILING yacht, being designed to attain the highest speed without the usual restrictive commercial considerations, provides an opportunity for the development of the ideal form of hull. If this is nicely balanced, the yacht keeps her course when heeled over, whereas if, on heeling, she tends to change course, she becomes a difficult boat to steer and can be described as unbalanced. In "A Law of Hydrostatics and its Influence on the Shapes of Sailing Yachts"—a paper read at the spring meeting of the Institution of Naval Architects held in March—Engineer Rear-Admiral Alfred Turner dealt with this question of balance. On heeling, the hull displaces an unsymmetrical volume of water, and may be considered as resting on the line of centres of buoyancy described as the metacentric shelf. This line does not form a plane curve; it may be very irregular, and from its irregularities there may arise a variable tendency to alter course according to angle of heel. The author investigates this by poising transparent paper patterns of a set of cross-sections and, after setting out Bouguer's law of balance with slight modifications, explains, by reference to the characteristics of some thirty-six vessels of which diagrams are given, the rules he has formulated.

In another paper, "The Development of the Two-stroke Cycle Oil Engine", read at this session, Mr. W. S. Burn, treating the subject from the marine point of view, explained its advantages over the four-stroke type in offering a cheaper, smaller, lighter and more efficient unit. The feature of first importance in its design is the evolution of a satisfactory method of scavenging, a process which has to be completed during the small movement of the piston and the small interval of time in which the exhaust ports are open. By means of a set of diagrams illustrating successful systems in use, the author explained their merits and classified them as uniflow or double-flow types. Scavenging being satisfactorily provided for, the two-stroke engine is shown to present, in other respects, a simpler problem for the designer owing to the greater freedom in arranging the combustion chamber, the cylinder head and piston crown, on each of which useful comment was made.

Marine steam boilers have, in the past, been regarded as immune from what is known as 'caustic embrittlement', but as in recent years a few cases have occurred in which the shells were found to be seriously affected and were condemned as unfit for further service, the problem has demanded the attention of marine engineers. The term is more picturesque than accurate, but the nature of the attack is characteristic and well defined, taking the form of intercrystalline fracture due to chemical action occurring only at the seams where two surfaces are in contact, and when the water is strongly alkaline and low in sulphates. The cracks follow the grain boundaries and are not transcrystalline as in the case of fatigue fractures. These points were illustrated by photomicrographs in a paper entitled "Note on the Chemical Intercrystalline Fracture of Riveted Joints in Boilers" read by Dr. S. F. Dorey, in which also he showed how the cracks in several joints examined were found to extend along the lines of rivet holes and along radial lines from these holes, invariably on the faces in contact.

While these results have always occurred in cases in which caustic soda was present, recent investigations suggest that the actual cause is the presence of sodium silicate in the soda or other chemicals used in the boilers. As soda was used in boilers long before caustic embrittlement was spoken of, the author thinks that possibly some difference in the method of manufacture of soda during the last thirty years may account for it and suggests that particulars of the analysis of the earlier supplies of soda may give some hint. He advises that care should be taken that nothing containing sodium silicate should be used in the treatment of boiler water and that, where soda is necessary, no more should be used than will maintain a neutral condition.

Science News a Century Ago

The Morse Recording Electric Telegraph

ON October 3, 1837, Samuel Finley Breece Morse, of the American artist and professor of the "Arts of Design" at the New York City University, filed in the United States Patent Office a "Caveat" comprising: "1st, a system of signs by which numbers and consequently words and sentences are signified; 2nd, a set of type adapted to regulate and communicate the signs, with cases for convenient keeping of the type, and rules in which to set up the type; 3rd, an apparatus called a port-rule for regulating the movement of the type-rules, which rules by means of the type in their turn regulate the times and intervals of the passage of electricity; 4th, a register which records the signs permanently; 5th, a dictionary or vocabulary of words numbered and adapted to this system of telegraph; 6th, modes of laying the conductors to preserve them from injury."

Morse was born in 1791. He was the eldest son of Jedidiah Morse (1761-1826), "the first American geographer". Educated at Yale College, he determined to be a painter, and at the Royal Academy in London in 1813 exhibited his picture "The Dying Hercules". During 1829-32 he paid his second visit to Europe, studying art in France and Italy, and it was on his passage home in the sailing ship *Sully* that, after a conversation on the possibility of sending electric currents along wires, he conceived the "Morse code". He had little scientific knowledge, but at the New York City University was assisted by Leonard W. Gale, professor of chemistry, who was acquainted with the work of Henry.

On September 4, 1837, with an apparatus made by Morse, a continuous dispatch was effected in the form of V-shaped lines inscribed on a paper fillet, consisting of the numbers "215-36-2-58-112-04-01837" which, interpreted by a numbered vocabulary, made the phrase "successful experiment with electric telegraph, September 4, 1837". Early in 1838, Morse discarded the numerals and employed an alphabet of 'dots and dashes'.

The Thermo-electric Light

IN the *London and Edinburgh Philosophical Magazine* of October 1837 is a communication from Francis Watkins, a partner in the firm of Watkins and Hill, opticians and philosophical instrument makers, of 5 Charing Cross, in which he says: "I

hope you will allow me to make known in your forthcoming publication a fact in thermo-electricity which I have observed since my last communication to you, and which I believe has not been noticed in print in this or any other country.

"With a pair of metallic elements, consisting of one bismuth and one antimony, weighing each five grains and measuring 0.5 of an inch long and 0.12 diameter, when their extremities were unevenly heated, I have obtained with a Henry's flat ribbon coil, a very perceptible and brilliant spark.

"I have had the pleasure of showing the experiment to MM. De la Rive, Plateau and Netschayef, and I need not add that these distinguished philosophers were much delighted on seeing the thermo-electric light developed by a single pair of metallic elements."

Medical Mission to China

THE following announcement is contained in the *British and Foreign Medical Review* of October, 1837: "The London Missionary Society is desirous of finding medical men adapted to execute its benevolent designs for the improvement of the vast and interesting population of China. To candidates properly qualified such an undertaking must be highly attractive. In a scientific point of view China presents a field of observation of great variety and extent. With slight exceptions the state of medical knowledge is extremely low and defective, and notwithstanding their inordinate national vanity, many of the inhabitants are beginning to recognize the superiority of Europeans in this as in many other departments. A competent endowment of medical science and more especially a talent for operative and ophthalmic surgery, would be a sure passport of popularity and reputation under such circumstances; and we can hardly imagine a situation more calculated to excite and gratify the honourable ambition and philanthropic feelings of generous and adventurous work."

The Medical Literature of Norway.

THE following extract is taken from a paper in the *British and Foreign Medical Review* of October, 1837, by Prof. Frederik Holst, professor of medicine at the Royal Frederik's University at Christiania: "The medical literature of Norway is but of small extent, and will probably always continue such in proportion to the population; as the latter is not great, the medical practitioners are but few, and the language of the country is understood by very few out of Scandinavia. Consequently, neither the medical man who might feel inclined to come forward as an author, nor the bookseller who is able to undertake the cost of printing the work, has the same encouragement as in other countries. It would therefore be unjust to consider the paucity of literary productions in that country as a proof of the incompetence of its medical men. The facilities of communication with other countries makes them pretty soon acquainted with foreign publications on subjects in their department; and in Norway there is no well-informed practitioner who does not take one or more of the best foreign medical journals, and procure the more important works by foreign medical writers. The medical works that have appeared in Norway have, in almost every instance, been called forth by particular occasions, or possess merely a private or local interest."

A. BARONI: Non-existence of bismuthous bromide, BiBr₃.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ASSISTANT WATER ENGINEER in the County Borough of Croydon—Town Clerk, application forms from Borough Engineer (October 5).
JUNIOR ASSISTANT in the Development Department, British Non-Ferrous Metals Research Association, Regent Buildings, Huston Street, N.W.1.—Secretary (October 8).

LECTURER IN BACTERIOLOGY in the Faculty of Medicine, University of Birmingham.—Secretary (October 9).

LECTURER IN CIVIL ENGINEERING at University College, Nottingham.—Registrar (October 15).

BROOKS ASSISTANT ENGINEER to the Rivers Mersey and Irwell Catchment Board—Engineer to the Board, Carrington Lane, Sale, Cheshire (October 16).

ASSISTANT (biology) in the Museum and Art Galleries, Paisley—The Clerk to the Committee, Young, Martin and Sayers, 4 St. Mirren Street, Paisley (October 20).

ASSISTANT DIRECTOR OF FISHERIES in the Straits Settlements—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, S.W.1 (October 31).

SIR HENRY ROYCE RESEARCH FELLOWSHIP for work on the common cold or on influenza—Registrar, The University, Manchester, 18 (October 31).

PROFESSOR OF SOCIAL SCIENCE in the University of Liverpool—The Registrar (November 15).

JUNIOR LECTURER and a **LECTURER IN ZOOLOGY** in the University of Cape Town—Secretary to the High Commissioner for the Union of South Africa, Trafalgar Square, London, W.O.2 (November 15).

TWO RESEARCH FELLOWSHIPS relative to the causation and pathology of rheumatic disease—Secretary, Empire Rheumatism Council, 1 Mire Court Buildings, Temple, M.O.4 (November 15).

TWO SENIOR ELECTRICAL ENGINEERS (temporary) at the Headquarters of the Air Ministry, Adastral House, Kingsway, W.O.2—Secretary (W.9).

ELECTRICAL ENGINEERS (temporary) in the Directorate of Works, Air Ministry, Adastral House, Kingsway, W.O.2—Secretary (W.9).

ASSISTANT MECHANICAL ENGINEER in the Locomotive, Carriage and Wagon Workshops of the South Indian Railway Co., Ltd.—Messrs Robert White and Partners, 3 Victoria Street, S.W.1.

State Intervention and Agriculture

STATE intervention in a particular industry is one of those subjects which most probably would have been rejected by the Council of the British Association had it not happily decided to include within its ambit the interactions of science and the life of the people. It is true that this development tends to bring the sciences into closer touch with economics and politics, but one day economics may be established as a fully inductive science, and knowledge obtained by impartial scientific inquiry will be the basis of political action.

State intervention is increasing everywhere, and for reasons which are not far to seek. Industrial and social relations generally have multiplied so greatly and become so exceedingly complex that only a supreme authority can co-ordinate them. An industrial system based upon the law of the jungle is no longer regarded either as ethical or efficient. Morality has not kept pace with material progress, and the basest uses are being made of some of the fruits of science and invention. The view that the functions of the State should be restricted to protecting its citizens against external aggression and maintaining justice between them is still valid if we accept a wider connotation of the word 'justice'. Probably most of us now consider it right that the State should control the conditions of industrial competition; that it should abolish privilege as a right to which no corresponding function is attached; that it should so far as possible give equal opportunity to all; and many think that it should secure to every worthy citizen a sufficiency of the basic necessities of life—wholesome food, clothing, shelter and facilities for re-creating mind and body.

Opposed to this growing recognition of the need for extended State action is the inborn longing

for individual freedom, and one of the major problems of civilization is how to reconcile the freedom required for individual development and self-expression with the restraints which the State must impose to save itself from anarchy and disruption, and to give every citizen a fair deal. No one with any faith in the future believes that these two ideals are fundamentally incompatible. Science, art and industry provide the knowledge and the means for attaining a full, free and happy life; and yet it eludes us—probably because the necessary emotional stimulus is lacking. The older religions no longer seem able to impart this stimulus. Can devotion to high ideals of conduct and attainment take their place? Man began by being a slave to his environment; he acquired the elements of freedom when he learned to adapt himself to it, and to co-operate with his fellows; his freedom grew as science taught him how, in a measure, to control his environment; it will grow still more as he learns to control himself and develop a social conscience. *Laissez-faire* is on its death-bed; State intervention, regulative, controlling or dominating is taking its place. To many it is a necessary evil, but it will persist so long as individuals and communities play a lone or selfish hand. The ecclesiastics who demand a 'change of heart' are right: "The solid ground of nature"—like patriotism—is not enough.

The incongruity of State regulation or control and personal freedom, in relation to agriculture, was well brought out by Mr. J. M. Caine in his presidential address to Section M (Agriculture) of the British Association. As assistant secretary to the Department of Agriculture for Scotland, his pronouncements were necessarily guarded, but it was clear that, although he recognizes the

inevitability of State intervention in existing circumstances, he deploras its extension, believing with the fourteenth century poet, Barbour, that "Freedom is ane noble thing". Liberation, if only partial, waits on the return of economic prosperity, and the road thereto lies in securing for farmers a fair share of the home market, and in inducing them to eat of the fruits of education and research. The personal factor, he is convinced, is still extremely important, and the progressive farmer is usually the last to seek aid from the State.

The trouble here is that it has always been found difficult to induce farmers, as a class, to adopt the innovations indicated by scientific research (Australian farmers took to the use of superphosphate twenty-five years after its value had been demonstrated). Great Britain possesses some research institutions of the highest class and a goodly number of well-equipped agricultural colleges and farm institutes, yet farmers fail to take full advantage of them. We have some of the best farmers in the world, but, according to high authorities, our general standard of farming is relatively low. In recent years farmers have had to contend with very low prices for their produce, and many of them have not been able to afford the purchase of new equipment; but prices are now better, and the time now appears opportune for making an organized effort to 'put over' to the rank and file of farmers the practical results of recent research. Farm-equipment, seed-dressing, grassland management, fertilizers and composts, ensilage, grass-drying, and farm accountancy are all subjects in which progress has been made and to which the farmers' attention should be directed. This question is of very wide import and might well be discussed at a future meeting of Section M.

No one will deny that the Ministry of Agriculture has been alive to the hardships and responsive to the importunities of farmers; with its aid the production of sugar-beet has increased from 102,000 tons in 1923 to 3½ million tons in 1936-7, and that of wheat by 44 per cent since 1932. It is now extending its protection to growers of barley and oats, and—what is more important—is coming to grips with the fundamental problems of maintaining the fertility of the soil, by paying half the delivered cost of lime and one quarter that of basic slag; and improving the health of livestock, by instituting a vastly extended veterinary service. Less directly, the Government has assisted agriculture by fathering the establishment of marketing boards for milk, potatoes, hops and bacon, and of

a commission for fat cattle. These boards have, in the main, succeeded in enabling producers to get better prices, in mitigating the effects of violent price fluctuations, and in controlling the quality of certain marketed produce. On the other hand, some of the schemes are exceedingly complicated and require an army of officials and employees to work them, whilst the criticism is often heard that consumers' interests have not been adequately safeguarded; for example, the price of milk for liquid consumption is held to be excessive. In Germany the cost of distributing milk is stated to be only about one half of what it is in Great Britain, so that by adopting a system of State control from cow to consumer similar to the German, we might save £10,000,000 a year on this item alone. Nothing appears to have been done to reduce the lamentable 'spread' between producers' and consumers' prices, and the conviction is growing that the Government must be driven to tackle the general problem of distribution and consumption, and to institute a census forthwith.

So far governmental efforts have appeared to concentrate on symptoms and palliatives rather than on radical cures, and legislation has been too piecemeal. Desperate diseases require desperate remedies, and that no doubt is one reason why Sir Daniel Hall, in the inter-sectional discussion at Nottingham on "Planning the Land of Britain", advocated the nationalization of the land, and why Prof. R. G. Stapledon has come reluctantly to the same conclusion in regard to the improvement of our upland pastures. Another urgent problem the solution of which is defying the efforts of the Government, is how to reconcile the demands of home farmers with those of producers in the self-governing Dominions; and no solution to the problem of increasing our supplies of home-grown food to make us secure in time of emergency is yet forthcoming.

These and other problems confronting agriculture and the community are of such magnitude and complexity that no one expects them to be resolved overnight. They transcend the ability of individuals and are therefore rightly passed on to the State. Many of them are of international moment, and most of them bear direct relation to the riddle of how to raise the purchasing power of the masses so as to give them a higher standard of life. The important thing is to rule out drift. Social change, like all change, is ineluctable, but it can be controlled and directed towards social betterment.

Ionospheric Disturbances, Fadeouts and Bright Hydrogen Solar Eruptions

By

Dr. D. F. Martyn and G. H. Munro, Australian Radio Research Board
A. J. Higgs and Dr. S. E. Williams, Commonwealth Solar Observatory, Canberra

FOR some months we have been recording daily the equivalent heights and reflection coefficients of the F_2 region of the ionosphere, for radio frequencies near to the critical penetration frequency of the region. Under these conditions, the

hours Eastern Australian Standard Time, is reproduced in Fig. 1. For reasons of lack of space, only the most marked period of the disturbance, between 0932 and 0955 is shown in the figure. The heights and intensities are recorded for

Fig. 1.

EFFECT OF BRIGHT HYDROGEN ERUPTION ON EQUIVALENT HEIGHTS AND ECHO INTENSITIES FROM F_2 REGION OF IONOSPHERE. VISUAL OBSERVATIONS WITH SPECTROHELIOSCOPE IN H_α SHOWED BRIGHT SPOT BETWEEN 0922 AND 0940 HOURS E.A.S.T.

recorded quantities are exceptionally sensitive to small changes in the electron density of the F_2 region.

Examination of our results reveals the frequent occurrence of a type of disturbance which has the following definite features:

(a) the equivalent height rises sharply in a period of a few minutes;

(b) the intensities of the reflected echoes decrease at the same time as (a);

(c) after some minutes the heights decrease and the intensities return to normal;

(d) although the disturbance may now be said to have ended, the F_2 region is left higher than before, although the F_2 electron density has returned to its original value, as evidenced by the separation of the ordinary and extraordinary magneto-ionic components, and other tests.

The record of a typical disturbance, which occurred on May 15, 1937, between 0920 and 1005

periods of 2½ minutes each successively, on frequencies of 9.75 and 10.7 mc./sec. The ground wave appears along the lower edge of the diagram, its intensity being measured by the breadth of the trace downwards and to the left, according to a technique as yet unpublished. It is seen that the ground wave is very weak for the lower frequency, while at 0945 and 0950 the ground wave on the higher frequency appears specially strong. The latter circumstance is due to the observer increasing the sensitivity of the receiver in an unavailing attempt to record echoes at this frequency. At 0932 are seen strong echoes from the F_2 region at equivalent heights of 400 and 295 km. These are respectively the ordinary and extraordinary components into which the wave is split by magnetic double refraction in this region. The doubly reflected echoes are seen above. The intensities of these echoes are indicated in the manner described above for the ground wave.

It is seen that the equivalent heights rise steadily until 0948, when the ordinary wave has penetrated the region while the extraordinary echo is of much reduced intensity. At 0955 the intensity of the extraordinary component is almost normal, but the equivalent height is now 365 km., which is much greater than obtained before the disturbance commenced. The intensity of the ordinary component returned to its normal value at 0957, and the heights returned to normal at 1005. On three occasions, namely, at 1250–1330 April 24, 1140–1220 May 25, and 1200–1300 June 11, the disturbances, while exhibiting all the characteristic features described above, were so pronounced that echoes practically disappeared. On each of these occasions, reference to the La Perouse receiving station of Amalgamated Wireless Australasia, Ltd., revealed that a fade-out of all signals from short-wave transmitting stations throughout Australia had occurred, while only a few overseas transmitters were heard, with greatly reduced intensity.

It is clear, therefore, that so-called 'fade-outs' are due to particularly strong ionospheric disturbances of the type described above.

The non-return of echoes from the ionosphere can be due to (α) a reduction of the electron density in the reflecting region, or to (β) an increase of ionization in an absorbing region. It is clear from the above that (α) does not occur in the F_2 region. For example, the disappearance of echoes on the higher frequency in Fig. 1 must be due to this cause. Calculation by well-established methods¹, of the reduction of the reflection coefficient before penetration occurs, reveals, however, that the observed reduction of ionization in F_2 is not by itself sufficient to account for the observed reduction of echo intensity.

We have obtained further information on this point from records showing equivalent height-frequency curves, which have been obtained automatically at half-hourly intervals with equipment formerly described². On some occasions, when a disturbance has been observed in progress, the operation of this apparatus has been quickened, so that it measured the ionization densities of the various reflecting regions E_1 , E_2 , F_1 , F_2 at five-minute intervals. From the auxiliary data obtained in this way it has been found that almost simultaneously with the reduction of ionization in the F_2 region, there occurs an increase in the ionization of the absorbing D region below 100 km. This is clearly shown by the weakening, and occasional complete disappearance of the E (and F) echoes obtained on low frequencies, although these echoes may be received almost unimpaired on higher frequencies.

It has been shown by Dellinger³ and others that fade-outs sometimes occur almost simultaneously

with bright hydrogen eruptions on the solar disk, although only a small fraction of observed eruptions appear to be effective in this connexion. We find strong evidence that *every* solar eruption observed at the Commonwealth Solar Observatory occurs almost simultaneously with an ionospheric disturbance of the type described above, although only a fraction of these disturbances are large enough to cause a complete 'fade-out'. Thus of forty-four eruptions observed during March–June 1937, forty-one were observed or estimated to begin within ten minutes of the beginning of an ionospheric disturbance, while only three eruptions produced no observable disturbance. It is further to be observed that, in the latter three cases, the eruptions followed closely after the occurrence of an earlier eruption which did produce an ionospheric disturbance. It appears likely, therefore, that in each of these three instances the ionosphere had not recovered from the effects of the earlier disturbance sufficiently to respond to the second eruption.

It is clear that all these effects must be due to sudden bursts of ultra-violet radiation from the eruptive area on the solar disk. In many cases the results show that the normal D region ionization is more than doubled during an eruption, although the eruptive area may be less than $1/2,000$ of the solar disk. It is clear, therefore, that the effective ultra-violet radiation from the eruptive area increases by a factor of some thousands during an eruption. Observations with the spectrohelioscope during eruptions show that the intensity of the first emission line of the Balmer series of hydrogen (H_α) increases by a factor of about ten in the eruptive area, but similar observations in the ultra-violet are, of course, unobtainable owing to atmospheric absorption.

We find very strong evidence that the major effects produced in the ionosphere during an eruption are due to solar emission of the Lyman resonance line L_α (1215.6 Å.) of hydrogen, which must be emitted in great intensity from the eruptive area.

No hydrogen radiation other than L_α is capable of penetrating the earth's atmosphere to the depth of the D region, but Hopfield⁴ has shown that air has just the necessary transparency over a limited spectral region around the wave-length of L_α . Moreover, no solar radiation capable of directly ionizing oxygen or nitrogen is capable of penetrating to the D region. Chapman and Price⁵ have pointed out, however, that the oxygen atom in the ^1S state resonates to L_α radiation (if a few angstroms wide) and is raised to the ^1P state. If a collision occurs in this state, it can lose an electron and 0.75 electron volts, thus reverting to the normal

state of ionized atomic oxygen. For this to happen it is obviously necessary that the life-time of the atom in the ^1P state must be comparable with, or greater than, the mean time interval between collisions. This condition is satisfied in the D region, where the electron collision frequency is approximately 5×10^7 per second. It is not likely to be satisfied in the E or higher regions, so that we should not expect increased ionization in these regions due to L_a radiation. The abundance of oxygen atoms in these regions is beyond doubt.

The decrease of ionization density in the F_1 region during an eruption is also explained by the great increase in L_a radiation. The radio data show conclusively that the region, and the atmosphere below to some yet undetermined level, is considerably heated and expanded during an eruption. This is evidenced by the pronounced rise in the real height of the F_1 region during an eruption, by the reduction of the density of the ionization in this region, by the comparatively rapid recovery of the F_1 ionization due to rapid cooling of the very hot F_1 region, and by the slower recovery of F_1 height due to the slower cooling of the less hot regions below. The work of G. H. Godfrey and W. L. Price, which is in course of publication, shows that in the absence of water vapour these regions would reach an equilibrium temperature of $3,200^\circ \text{K.}$ due to the absorption by oxygen of solar ultra-violet radiation of wave-lengths about $1450 \text{ \AA.}$ It is the presence of water vapour, in concentration of about one part in ten thousand by volume, which keeps the temperature down to the values between $1,000^\circ \text{K.}$ and $2,000 \text{ K.}$ which are found experimentally by Martyn and Pulley* in the F_1 region.

It has been recently shown by Rathenau† that water vapour shows strong absorption bands at the wave-length of L_a , such absorption leading to dissociation of the H_2O molecule into H and OH^* .

It is clear, therefore, that the strong L_a solar radiation during an eruption must dissociate much of the water vapour present in the upper atmosphere, so leading to higher equilibrium temperatures in the ionosphere. The application of Godfrey and Price's calculations shows that these temperatures are attained in a few minutes, and leads to a detailed explanation of the observed phenomena in the F_1 region during an eruption.

The origin of the numerous ionized levels of the ionosphere is still unknown, progress having been impeded by lack of knowledge of the solar radiation in the ultra-violet. The assumption of black body radiation in this region only increases the difficulties of interpretation by providing an infinite variety of ionizing radiation. It is a fortunate circumstance that the increased radiation during an eruption is confined to relatively few wave-lengths, with L_a almost certainly predominant. We believe that the study of the behaviour of the ionosphere while the sun is providing increased energy at these relatively few wave-lengths must greatly increase our knowledge of the normal structure of the ionosphere, and of the normal solar ultra-violet radiation. With this object in view we are now studying the effects of solar eruptions on the E_1 , E_2 , F_1 and G regions, in all of which smaller but appreciable changes occur.

This work is published by permission of the Radio Research Board of the Commonwealth Council for Scientific and Industrial Research, and of the director of the Commonwealth Solar Observatory.

Geographical and Cultural Regions

A JOINT discussion between members of Section E (Geography) and Section H (Anthropology) was held at the British Association meeting at Nottingham on the subject of geographical and cultural regions. The primary object was to clarify the concepts of regional divisions of the earth's surface from various points of view.

A large measure of agreement on the fundamental principles of regional division from the point of view of the geographer was revealed. Its essential object is to distinguish different environments, and there was no divergence from the view that the most permanent contrasts, and those most

important in relation to human life, are determined by natural factors (position, physical features, structure, climate, soils and vegetation). The total complex of conditions characterizing the personality of any such 'environment region' is, however, in practically every case profoundly modified by man, who must himself be included as one of the creative factors. Entirely 'natural' regions are now comparatively rare; for example, it was pointed out that very little of the tropical forest of Africa is in a true sense primitive. Subject to this qualification, the concept of major natural regions, as worked out at the beginning of the century by

Prof. Herbertson of Oxford, is of great and lasting value.

It is important, however, to distinguish two aspects of regional division. Regional schemes such as that of Herbertson are *generic* in character. A type is defined, based on fundamental criteria of climate and other factors, and its distribution over the earth's surface examined. All the representatives of the type broadly resemble each other in these particular respects and their 'intrinsic conditions' are comparable. But generic classifications of this kind cannot take into account the factor of geographical orientation, which in its influence on the evolution of human societies and the moulding of the *genre de vie* is often quite as important as the intrinsic conditions. The Sahara and the Atacama in Herbertson's scheme both belong to the category of hot deserts; but the geographical position of the Sahara between the Mediterranean lands and tropical Africa has profoundly influenced the evolution of its trading societies and differentiated its human life from that of the Atacama. So, too, while there is a 'Mediterranean' type of climate, vegetation and production, which is found in five or six widely separated parts of the world, the Mediterranean region of the Old World in the sum total of its conditions and in its geographical setting has no real parallel elsewhere.

Thus, apart from generic classifications, the attempt is made by geographers to distinguish what may be termed *specific* regions with a particular location and a combination of conditions found nowhere else. There are different 'orders' of such regions, ranging from the *pays* of France (Beauce, Brie, etc.) to such large concepts as 'Western Europe'. When over wide areas there is found a particular set of intrinsic conditions in combination with a very definite geographical orientation, we have distinctive theatres of human life which are characterized by a series of closely linked physical and human phenomena. Examples of such large 'human provinces', if the phrase may be allowed, are North China (north of the great climatic, vegetational and economic divide of the Tsin-ling shan), the Lower Yang-tze Basin (below the Gorges) and South-East China (south and east of the Nan-ling and its continuations). In such attempts to define large specific regions it is often necessary to recognize transitional zones and to admit that human agency, as in the case of the North German Lowlands in recent times, may change considerably not only the intrinsic conditions but also the value of the geographical orientation.

The discussion at Nottingham on the concept of cultural regions and their relationship to geographical divisions of the earth's surface was mainly negative. On the ground that race,

religion and language are all unsatisfactory and dangerous as criteria, several of the anthropologists present were unwilling to admit the validity of the concept of cultural regions, except in respect of limited areas defined in terms of material culture-traits such as those which Mr. Clark Wissler has determined for aboriginal North America. Owing to its isolation and comparative immunity from new waves of cultural influence, Pre-Columbian North America presented a more favourable field than Asia or Africa for the establishment of relatively stable culture-complexes broadly corresponding to natural 'food-regions'. But even these passed through many phases and interacted in complex ways before the final disintegration caused by the advent of the white man.

Admitting the force of these contentions, the question remains whether it is not still legitimate and indeed important to distinguish regional types of civilization. A notable passage in Mr. R. F. Hudson's scholarly work on "Europe and China" is worth recalling:

"There is a hierarchy and ranking of nationalities in accordance with degrees of community or separateness in cultural inheritance. There is the supreme nationality which is mankind. Within this greatest whole are the few great unities formed by continuous dominant traditions of original civilisation, and within these again are the many lesser groups, determined mainly by present spoken language, which are the only 'nations' known in ordinary speech.

"Europe and China are nations of the first division of mankind: they are great continuities of historical development which may embrace many distinct languages and political units. . . . The real unity in each case has been one of cultural tradition. Europeans are all peoples and states deriving their dominant cultural form directly or indirectly from Hellenism, Chinese those deriving it from the 'Chinese' empire of the Hwang-ho basin in the first millennium B.C."

Is it denied that, in spite of the complexities and new ideologies of the modern world, there are still certain "great unities formed by continuous dominant traditions of original civilisation"? Is it no longer valid to make the distinction between the European and the Chinese type of civilization? Has not the real unity of China been in a broad sense 'cultural'? Or, if 'culture' must be used in a more restricted sense, what other term should be employed to express a unity that has been immensely powerful and yet has been neither national nor political? These questions may be asked with full consciousness of the intricacy of modern civilization and the possibility of rapid change in cultural affinities such as seems to be illustrated by the Turkish national State since the Great War.

P. M. ROXBY.

Chemistry of Building Materials

AT the meeting on September 7 of Section B (Chemistry) of the British Association, there was a symposium on "The Chemistry of Building Materials". After an introduction by Dr. B. E. Stradling (director of the Building Research Station), papers were presented by Dr. F. M. Lee (Building Research Station) on "Some Problems in the Study of Hydraulic Cements", Dr. J. S. Dunn (Imperial Chemical Industries, Ltd.) on "Calcium Sulphate Plasters; Setting, Retarders and Accelerators", Mr. F. H. Clews, Mr. H. H. Macey and Dr. G. R. Rigby (British Refractories Research Association) on "Some Important Properties of Clay", and Dr. D. G. R. Bonnell (Building Research Station) on "Some Problems connected with Porous Building Materials".

Building presents an excellent example of a traditional industry in the stage of transition to an applied science. It is an industry founded originally on craft and based on rules of experience which have become enshrined in traditional methods. To the older building materials such as timber, stone, burnt clay and lime, there has been added in modern times a host of new products, whilst the demand for speed and economy in building has resulted in numerous changes in methods. These changes have often been in the nature of extensions and modifications of traditional processes, but they have been made without that full knowledge of the reasons for the success of the traditional methods which is necessary if development is to have a sure basis and to be other than the slow and costly traditional method of trial and error. Modern conditions have necessitated, therefore, not only the examination of the newer materials and processes, but also the study of the traditional materials and of the reasons for the success of the traditional methods.

This is well exemplified in the craft of the plasterer. The production of lime was formerly a local industry, and the craft by long experience had become adapted to the properties of the local materials. The modern development of large-scale production has led to the wide distribution of materials which, though outwardly similar, differ in properties from those to which the craftsman was accustomed. Calcium sulphate plasters have been added as an additional plastering medium, but materials of this class, differing widely in properties, and in the methods necessary for their successful handling, are distributed under trade names giving no clue as to the type to which they belong. The substitution of Portland cement mortar for lime mortar in rendering and stucco,

again without adequate appreciation of the very different properties given to the finished product, has been a very common cause of trouble.

As was pointed out by Dr. Stradling, the craftsman in lime and plaster controls a chemical reaction of which he knows nothing. While working with materials in which he had long experience, the craftsman could produce excellent work; with materials of different physical properties and rates of reaction, however good these materials might be, there entered factors to which he was unaccustomed, and of which he had no warning, and his craft suffered in consequence.

The problems in building to-day are, however, not only due to insufficient knowledge of the fundamental properties of its materials of construction, but also, and in considerable degree, to insufficient dissemination of the existing knowledge among architects, builders, engineers and craftsmen. Whilst research on materials is now proceeding at a rapid rate in many countries, the need for further education in the building industry is only too clear.

The discussion at the meeting of Section B could inevitably only cover a small part of the field indicated by its title, but it sufficed to bring forward many interesting problems.

Apart from the metals and igneous rocks, all building materials are porous and capable of absorbing water to some extent. Changes in moisture content, not only on first drying, but also in subsequent use, produce accompanying changes in volume and in other physical properties such as strength and elasticity, while the movement of water, carrying soluble salts in solution, gives rise to surface efflorescence and to decay of masonry and brickwork. The change in volume is responsible for much of the cracking found in buildings. In practice it is relieved to some extent by the ability of materials to creep, or undergo plastic deformation under load. Though much work has been done on shrinkage and creep, there is still need for further study of moisture movements under conditions of restraint, such as normally occur in building. The general phenomenon of volume change in porous solids has as yet interested chemists relatively little though it offers a promising field for research. The work of Meehan and Bangham on the expansion of charcoal by sorption of gases and vapours is suggestive in this connexion.

Calcium sulphate plasters can be grouped generally into the hemihydrate and the anhydrite types, the latter being produced by the burning of gypsum

at relatively high temperatures or from the natural mineral. The system calcium sulphate-water is of the simplest binary type, but despite much work since Lavoisier's original contribution in 1765, the problem of the dehydration products of gypsum has never appeared fully solved. It has usually been considered that the partial dehydration of gypsum results in the formation of the hemihydrate, $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$, but Dr. Dunn reported that the crystal form of this compound remains unaffected, with but minor changes in the lattice constants, with water contents ranging from 0 to 0.65 molecules of water. It is considered probable, therefore, that there is a zeolitic series with $3\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ and CaSO_4 as end members. Plasters containing the so-called hemihydrate usually require to be retarded as otherwise their rate of set is too rapid for normal use in building. Two types of retarder can be distinguished, one reducing the rate of nucleus formation and the other acting similarly, but, in addition, modifying the habit of the gypsum crystals, giving a relatively slower rate of growth along the *c* axis. The rate of set of anhydrite plasters is very slow and, in practice, an addition of an accelerator is required. In general the hydration is accelerated by sulphates of the alkali and other metals, but the most effective catalysts are those combining an alkali metal sulphate with the sulphate of another metal such as zinc, the effect being more than additive and an optimum ratio existing for the two sulphates. The alkali metals accelerate the growth of gypsum crystals most at right angles to the *c* axis, while zinc sulphate is more specific for growth parallel to that axis. This observation takes the explanation of the action of a two-component catalyst one stage forward, but the problem of how each catalyst stimulates crystal growth still remains.

Though the most obvious property required in a cement is that of developing strength, in practice this presents few problems compared with those arising from volume change and physical and chemical decay. The heat of hydration of Portland cement, which may amount to a hundred calories per gram, is a source of considerable trouble in concrete structures of large mass. The internal temperature in concrete dams, for example, may rise as much as 50°C . above the original temperature of the materials, and the thermal contraction which takes place during subsequent cooling is the main cause of cracking in such structures. The production of cements with a reduced heat of hydration, and their utilization in recent work, such as Boulder Dam on the Colorado River, U.S.A., can be traced back to the much increased knowledge of the constitution of Portland cement which has resulted from phase equilibrium studies on many of the oxide systems involved.

The relative properties of vitreous and crystalline phases of the same gross composition is a matter of much interest in cement technology at the present time. During the burning of Portland cement, some 20-30 per cent of the mass passes into the liquid condition, but the extent to which this liquid crystallizes on cooling, or supercools to form a glass, probably varies considerably. There is evidence that unexplained differences in properties of cements of similar composition and fineness may have their origin in variations of this kind.

Clay is amongst the oldest of the raw materials of building and it has been successfully moulded, burnt and used for some thousands of years without any scientific knowledge of its chemical constitution or physical properties. A certain degree of control was, however, formerly exercised by Acts of Parliament. In 1477, in the reign of Edward IV, an Act required that the clay should be dug before November 1, turned over before February 1 and not used before March 1. Even so late as the reign of George III, there came an added requirement that the clay should be turned between February 1 and the time of moulding of the bricks. The reduction or, in some cases, entire elimination of the time of weathering of the raw clay, together with the speeding-up of drying and other processes, have created many new technical problems. The large-scale production of burnt clay products demands, therefore, if it is to be conducted on economic lines, a degree of control both of materials and processes which was quite foreign to the older small-scale industry.

The mineralogy of raw clay has made striking advances in recent years, but the chemical changes which occur on burning are still a matter of controversy. Plasticity, that physical property by which clays are characterized, remains a much confused subject. In many of the experimental methods used for its determination in the clay industry, properties other than plasticity enter, and a return to methods which are fundamentally simple, such as the measurement of deformation in torsion or tension, appears necessary. Problems of drying play a large part in manufacture, and most manufacturers use unnecessarily long drying periods as an insurance against losses by cracking. This could be avoided by the application of adequate knowledge of the properties of a clay. The temperature of drying is important, there being a temperature at which the safe rate of drying is a maximum; the tendency to crack is greater above and below this temperature. It appears that the decrease in viscosity of water with rise in temperature is offset at the higher temperatures by the decrease in the tensile strength of the clay.

F. M. L.

The British Association and the Indian Science Congress

A Scientific Delegation to India

ARRANGEMENTS for a scientific delegation from Great Britain to India this winter are nearing completion. The Indian Science Congress Association, which holds annual meetings in different parts of India of individual scientific workers and others, and functions much on the lines of the British Association for the Advancement of Science, is approaching the celebration of its jubilee (twenty-fifth) session at the meeting to be held in Calcutta in January next. The Association invited the co-operation of the British Association in forming a representative visiting delegation from this country and others, and the General Committee of the British Association eagerly accepted the invitation, which was, in effect, to make a new use of the mechanism of the Association, and one which is felt to suggest far-reaching implications. It is common knowledge that the British Association has sometimes held its own annual meetings overseas, at the invitation of Dominion Governments and institutions. But it has never before been asked to co-operate in organizing a scientific delegation apart from its own annual meetings—and if this can be done for India, why not for other parts of the Empire in which conditions would not permit of a meeting of the Association on ordinary lines? But this is to anticipate: the present notice is concerned with the Indian meeting.

It was arranged with the Indian Science Congress Association that invitations should be extended, through and by the British Association, to a large number of eminent scientific workers in Great Britain, in part on nominations received from India, and for the rest on representative standing in the British Association. The Indian Association itself has invited certain representatives from foreign countries, and also from Great Britain in a few departments of work which find more prominent places in the Indian Association than in our own. Lord Rutherford accepted the Indian Association's request to preside over the joint congress, to the immense satisfaction of both British and Indian colleagues. The total number of the party, including delegates and persons accompanying them, is 94 at the moment of writing; but this is subject to some addition—not, it is to be hoped, to subtraction.

The programme in India is being arranged by the Indian Science Congress Association, and the presidents of the sections for the meeting are all residents in India; but the visiting delegates may

be expected to take an active part in the proceedings. The meeting in Calcutta will run from January 3 until January 9, and will be preceded and followed by tours through India, during which visits will be paid to various university and other centres of scientific interest, and it is understood that some of the visiting delegates will be invited to lecture.

The great majority of the visiting party will sail on the P. and O. steamer *Cathay* on November 28 (or will overtake her at Marseilles by leaving London on December 2) and are due at Bombay on December 16. Two days will be devoted there to reception and sight-seeing, and the party will then leave in a special train or trains in which they will live, strenuously no doubt but in the best of comfort which the Indian railways can provide, for the next twelve days. In the course of this journey they will visit Hyderabad (by the special invitation of the Nizam's Government), Agra, Delhi, Dehra Dun, and Benares, besides intermediate points of interest, where scientific and university institutions in particular will be inspected. There will be some opportunity for short journeys from Calcutta before the meeting of the Congress, including field excursions to the coalfields, Tatanagar, Darjeeling, ancient 'Gaur', the Sundarbans and the Assam oilfields, and after the meeting a further tour is planned to include Madras and Bangalore. Many of the delegation, however, having special interests and contacts in India, will substitute for this second tour individual visits to various places, and full facilities will be given to them to do so. Nor will the whole party be gathered together for the homeward voyage, though a substantial proportion of it will return from Bombay on the S.S. *Strathaird*, which will bring passengers to England on February 3, or a few days earlier by the overland journey from Marseilles.

The fund necessary in connexion with this occasion has been raised partly by the Indian Association, partly by the British Association from interested firms and individuals at home, and partly by means of a contribution from the funds of the British Association itself, which last is additional evidence, if any were needed, of the full appreciation of the importance of the occasion by the Council and General Committee of the senior body, as well as of the high compliment paid to it by the Indian Association in inviting its co-operation.

Obituary Notices

Prof. V. L. Kellogg

IN the death of Vernon Lyman Kellogg, which took place at Hartford sanatorium (Conn.) on August 8 last, the United States loses an eminent citizen and one who was a leading figure in the scientific life of that country. Born at Emporia, Kansas, in 1867, he graduated at the University of Kansas in 1889 and at Cornell University in 1891. His academic training was primarily as a zoologist and was continued in Paris and in Leipzig.

Although a man of broad zoological interests, Kellogg's scientific papers were almost entirely concerned with entomology. For a few years he taught that branch of the subject at Kansas University and afterwards he became professor of entomology and lecturer in bionomics at Stanford University. In 1908 he married Miss Charlotte Hoffman of Oakland, California. During his long period of tenure at Stanford, he was closely associated with the late David Starr Jordan, in collaboration with whom he wrote several books on diverse aspects of general zoology.

Kellogg's career at Stanford University virtually came to an end with the advent of the Great War. It was through the influence of Herbert Hoover that Kellogg was seconded for work in connexion with the American Relief Commission in Europe. Here his organizing capacity found scope, and he rapidly came into prominence owing to the leading part he performed in the Commission's activities. From 1917 until 1919 he was director in Brussels of this Commission for Belgium. His labours, on behalf of the benevolent efforts made by the United States, took him also to Poland and to Russia. The services which he rendered in organizing relief and other measures, during and after the War, received recognition by the bestowal upon him of decorations by France, Belgium and Poland.

On returning to the United States, Kellogg resigned his position at Stanford University, which he had held from 1894 until 1920. He had lately become permanent secretary of the National Research Council, an office which he administered until he retired from the post at the end of 1931. Kellogg's main interests were no longer in academic work, and he embarked upon what had been described as his period of greatest influence and accomplishment. In his capacity as secretary he played a major part in organizing the National Research Council. Being also a member of the National Academy of Sciences, a trustee of the Rockefeller Foundation and a member of its executive committee, and of other bodies, he was able to do much towards moulding the trend of scientific activities in America. Prof. R. A. Millikan, writing in *Science* of September 3, recounts that about 1930 Kellogg found himself to be the victim of an incurable malady known as Parkinson's disease (paralysis agitans). The fortitude with which he

faced this sentence, with unimpaired mind and failing body, won the admiration of personal friends. He only missed by a few months attaining his seventieth birthday.

Kellogg's contributions to entomology were in taxonomy and anatomy. For a number of years he was the leading authority on bird parasites or Mallophaga. His other papers were chiefly concerned with the structure of Diptera, and he also made a special study of the family Blepharoceridae and their larvae. His monograph on this group, and also that on the Mallophaga, formed parts of the "Genera Insectorum". His writings also include anatomical and other articles on Lepidoptera. Most of his papers were short, but they usually brought to light new or interesting features. His books were of a more general character and included "American Insects", 1904; "Evolution and Animal Life" (with D. S. Jordan), 1907; "Darwinism To-day", 1907; "Economic Zoology and Entomology" (with R. W. Doane), 1915; "Mind and Heredity", 1923; "Evolution", 1924, and several others.

During the War years, and shortly afterwards, Kellogg wrote various books of a different character—they were incidental to that upheaval in Europe and had particular reference to its political and economic outcome. These writings made his name familiar among his countrymen as that of a notable exponent of those times.

A. D. IMMS.

Mr. F. C. Thompson

FREDERICK CHARLES THOMPSON, lecturer in the Leather Industries Department and research assistant in the Procter International Research Laboratory of the University of Leeds, died on September 4 at the age of forty-six years. He received his early education in a Leeds secondary school and then followed the honours course in pure chemistry at the University of Leeds, graduating in 1911. Two years later he obtained an honours degree in the chemistry of leather manufacture, and in the same year was appointed to the staff of the Leather Industries Department as assistant lecturer and demonstrator under the late Prof. H. R. Procter.

In 1913, Mr. Thompson became research assistant in the Procter International Laboratory and in 1923 was made a lecturer in the Leather Industries Department. He carried out a great variety of investigations on subjects connected with the applications of protein chemistry to leather manufacture independently and in association with Prof. H. R. Procter, Prof. D. McCandlish and Mr. W. R. Atkin, a fellow lecturer in the Department. Recently, in collaboration with Mr. Atkin, he re-wrote Procter's "Leather Chemists Pocket Book", and this revised enlarged edition is generally regarded as the standard analytical text-book for the leather chemist.

Mr. Thompson was an authority on the application to problems of the leather trade, of electrometric and colorimetric titration of reactions and was frequently consulted by workers in other branches of applied science. In recent years he collaborated with Dr. J. Gordon of the Leeds Medical School in research work upon the complex subject of immunity, where Mr. Thompson's knowledge of protein chemistry proved useful, and several joint papers have been published by them in the *British Journal of Experimental Pathology*.

Mr. Thompson enjoyed the complete confidence of his colleagues in the International Society of Leather Trades' Chemists—an organization with branches in almost every civilized country in the world. After occupying many responsible positions as chairman of commissions, he became president of the Society in 1932 and held the office for two years. One notable contribution to the work of the Society which has earned the lasting gratitude of leather chemists was made jointly with his colleague Mr. W. R. Atkin. For many years difficulty had been experienced in securing uniform supplies of hide powder, an essential material for the quantitative estimation of tannin in tanning materials used commercially. By their joint research, Thompson and Atkin established the cause of this variation and showed how it might be readily overcome. As a result of this work, far greater concordance of results is now secured in quantitative tannin analysis than was previously possible.

Mr. Thompson was a tutor of the University of Leeds, and for several years had been a member of the local committee of the Association of University Teachers. He had many interests outside university life—chief amongst them being welfare work amongst boys. He holds the record for longest continuous service with the Boys' Brigade in Leeds. Under his captaincy his Company won all the trophies open to competition, and held the battalion ambulance cup continuously for twenty-three years. For many years he was superintendent of the Burley Methodist Church Sunday School. He was interested in music and his ability as a violinist resulted in his association with several amateur orchestras. In 1919 he married Miss M. Hampshire, and she survives him.

D. McC.

Prof. A. W. Gibb

PROF. A. W. GIBB, first Kilgour professor of geology in the University of Aberdeen, died on July 12 at the age of seventy-three years.

Alfred William Gibb was born and educated in Aberdeen. After taking the degree of master of arts at the University of Aberdeen, he spent some years in teaching and in business before resuming his studies. He was one of the first to graduate at Aberdeen with the newly established degree of bachelor of science, and soon after he became assistant to the professor of natural history. In Aberdeen at this time, 1896, the teaching of geology and zoology was carried on in the one department. Fortunately, the interests of the professor, Henry Alwyn Nicholson, were keenly palaeontological and his enthusiasm and care in developing the geological side of his teaching

were shared by his assistant. When the late Sir J. Arthur Thomson succeeded Nicholson, he left the geology teaching entirely to Gibb. In 1908, a lectureship independent of the Natural History Department was established, and in 1922, the Kilgour chair of geology was founded. To each, in turn, Gibb was appointed, and he was responsible for the planning and development of the Department of Geology in Marischal College.

Instruction in the mineralogical and petrological aspects of geology was Prof. Gibb's personal responsibility. To this end, he spent his spare time studying with Miers and Judd, and in Heidelberg with Rosenbusch. In 1908 he was awarded a doctorate in science for a thesis describing the rocks of the basic complex of Balhelvie, and he communicated several papers on diverse aspects of local geology to the Geological Society of Edinburgh.

Prof. Gibb's main interest was his 'ordinary' class, the first-year class for arts and science students. His lectures were extraordinarily popular, vying with those of his colleague, J. Arthur Thomson, and infecting generations of students with a vital interest in the subject which he expounded with such fascination. He had been teaching for forty years when he was forced by ill-health to retire in 1936, and the news of his death will be received with the regret that he was unable to enjoy fully the peace of his retirement.

Prof. A. Heim, For. Mem. R.S.

A CORRESPONDENT writes:

"Though his name will always be associated with his studies on Alpine structure, the part of Prof. Albert Heim as the founder of the Swiss Seismological Commission deserves to be remembered. In 1878, the first year of its existence, the Commission consisted of seven members, with Prof. A. Forster of Bern as president and Heim as secretary. To Heim was also assigned the task of collecting observations from Zurich, Uri and other cantons. Though its work was taken over in 1913 by the Swiss Meteorological Office, the Commission, re-named as the Swiss Earthquake Service, may claim to be the oldest, and by no means the least useful, of all existing committees for the study of earthquakes."

We regret to announce the following deaths:

Major B. F. S. Baden-Powell, known for his pioneer work in aeronautics, formerly president of the Royal Aeronautical Society, on October 3, aged seventy-seven years.

Mr. Richard Inwards, a former president of the Royal Meteorological Society, on September 30, aged ninety-seven years.

Mr. Arthur Kitson, who was early associated with electric lighting and the telephone, and invented the Kitson light, among numerous other devices, aged seventy-eight years.

Prof. W. St. Clair Symmers, emeritus professor of pathology in the Queen's University, Belfast, on October 4, aged seventy-four years.

News and Views

Biometry at University College, London

FROM the beginning of the present session, Prof. J. B. S. Haldane changes his duties by taking on those of the first Weldon professor of biometry, and he is the first holder of a chair in the subject at any British university. The post was founded by a bequest left last year by Mrs. F. J. Weldon in memory of her husband, Prof. W. F. R. Weldon, who was one of the original editors of *Biometrika*. Prof. Haldane will give the first of a course of ten lectures on biometry at 5 p.m. on October 12. In 1895 Karl Pearson gave his first course on the mathematical theory of statistics at University College, when he was professor of applied mathematics and mechanics. The Biometric Laboratory originated at this time. In 1907 he took over the Eugenics Laboratory from Sir Francis Galton. On his death two years later, the latter left the residue of his estate for the founding of a professorship and Laboratory of National Eugenics and Karl Pearson became the first Galton professor. For the next twenty years, research and teaching in eugenics, statistics and biometry were carried out in the same Department, known as that of Applied Statistics. On the retirement of the director in 1933, separate departments for the first two of these subjects were instituted, and there are now chairs for all three at the College where they first obtained academic recognition.

Ionospheric Disturbances and Solar Eruptions

DR. D. F. MARTYN, Messrs. G. H. Munro and A. J. Higgs, and Dr. S. E. Williams, in a communication which appears on page 603, show evidence that a type of ionospheric disturbance accompanies every bright hydrogen solar eruption. The main features of the disturbance are an increase of ionization in the *D* region and a heating effect in and below the *F*₂ region. When the disturbances are large they cause 'fade-outs' in short-wave communication. It is concluded that these effects are due to a greatly increased emission of the hydrogen resonance line *L*_α from the eruptive area. This causes ionization of atomic oxygen in the *D* region, and dissociates the water vapour in the *F*₂ region, thus raising the equilibrium temperature. Further evidence of a connexion between solar activity and short-wave radio 'fade-outs' is given in the note entitled "An Active Sunspot" on page 616 of this issue.

A New Permanent Water-Repellant for Textiles

A NEW compound of exceptional interest to both chemists and textile manufacturers is the subject of an exhibition housed at Dorland House, S.W.1, on October 5-8. This preparation, which has been given the name "Velan", has been developed during the past three years at the Manchester laboratories of Imperial Chemical Industries, Ltd., as a universal water-proofing agent for textile goods. Information

concerning the chemical composition of Velan is not yet available, but it would appear to be a complex organic substance which reacts with both hydroxyl and amino groups and on that account is able to combine with both animal and vegetable fibres. For the impregnation of textiles, Velan is used in the form of aqueous dispersions, which are readily preparable from the substance without the aid of supplementary agents. The impregnated fabrics are dried, and combination between the reagent and the textile fibres is afterwards effected by heating at a temperature of 100°-150° C. It is the last stage of the process which gives permanence to the proofing.

VELAN is claimed to be the first water-repellant for textiles which will remain permanent during repeated washing, laundering and dry-cleaning processes. Further, the compound is said to be unique among proofing agents in that it imparts softness and suppleness to fabrics. Unlike rubber or cellulose lacquer waterproofings, Velan does not affect the interstices of textiles and render them impermeable to air. The proofing process has proved satisfactory with cotton, wool, natural and artificial silk, straw, etc., though cotton seems to be somewhat more satisfactory than other textiles from the point of view of the permanence of the proofing. In view of these advantages, and the fact that processing does not add greatly to the cost of manufacture, Velan should find a wide range of applications in the textile industries.

Aid for Intellectual Unemployed in France

INTELLECTUAL workers, including men of science, writers, artists and others, have suffered no less than industrial workers during the recent years of economic unrest. In 1934 an organization was established in France with the object of providing socially useful work for the unemployed professional men and women. A list of work to be done was prepared and private donations were obtained to support the enterprise in order to see whether the idea had a practical value. Thus, in 1934 and 1935 a considerable number of unemployed were engaged in preparing a complete list of benevolent associations existing in France since 1901. The "Confédération des travailleurs intellectuels", consisting of more than 200,000 workers from various professional groups, also had the problem of intellectual unemployment under consideration. "L'Entr'aide des Travailleurs Intellectuels" (E.T.I.) was organized in order to examine the situation and to find ways and means of giving efficient assistance. The poor financial state of France excluded all possibility of help from the Government, and it was impossible to rely upon private donations. A campaign was therefore begun to obtain from the authorities permission to issue special stamps of different values, with a small surcharge, the surcharge being destined for the intellectual unemployed. The

campaign succeeded in obtaining a resolution published in the *Journal Officiel* on May 27, 1936, by which the issue of special stamps was confirmed, and the E.T.I. was entrusted with the receipt and distribution of the funds collected, under conditions drawn up by the council of the E.T.I., the Minister of National Education and the Postmaster-General.

It was considered more useful to spend the money on work in science, literature and art, than in distributing doles, the work being carried on so long as the funds permitted under approved conditions. The work thus provided may not, of course, be adapted to the special qualifications of every unemployed person, but they are engaged for six months to do some socially useful work, unless they find employment in their own field. Up to January 1, 1937, the French Post Office paid over to the E.T.I. about a million francs under this scheme. This sum is due mainly to philatelists and stamp-dealers; for the success of the scheme, it is necessary that the public generally should take part in this social and humane work. At present the following stamps have been issued:

Fig. 1.

Letters abroad:

1 fr. 50 c. surcharge 50 c. (see Fig. 1)

Post-cards abroad:

90 c. " 10 c.

Internal correspondence:

50 c. " 10 c. and 20 c.
(three kinds of stamp)
30 c. " 10 c.

These special stamps are available at any post office in France and at the E.T.I. (12 rue Henner, Paris IX), where they can be supplied in any quantity required.

Ancient Monuments in France

At the close of September the Commission des Monuments Historiques of France completed a hundred years of its existence. Although at one time subjected to no little criticism, instructed and otherwise, since the War, when it has included among its members the most distinguished of French archaeologists, its activities, both in the preservation and protection of buildings of historic interest and in its care for the antiquities of France generally, have deserved the highest praise. Notwithstanding limitations, of which the members of the Commission are even more fully conscious than expert opinion among the outside public, its control, advice and assistance in bringing to light, preserving and making

accessible the evidence from the prehistoric sites of France, which is now a world-wide possession of archaeological science, has earned the gratitude of every student of antiquity. Even better known to the travelling public, however, are the efforts which have preserved from decay and no less from vandalism the structures of the Middle Ages and of the Roman period. Among the latter the wonderful series of monuments of Roman culture, such as those at Orange, at Nîmes and at Arles, can never be forgotten by anyone who has passed through Provence. Among the latest achievements of the Commission is the excavation of the Roman theatre of Vienne, south of Lyons, which is not an amphitheatre of the more usual type, but is cut out of the side of the hill and necessitated an excavation more than sixty feet deep to bring to light the lowest tier of seats. The completion of the excavation is to be celebrated by a number of theatrical performances to be given on the stage next year similar to those now given annually in the amphitheatre at Orange.

'Shiva's Temple', Arizona

DR. HAROLD ANTHONY, leader of the Patterson-American Museum Grand Canyon Expedition, on his return to New York, gave a preliminary account of the results obtained during his four days' stay on September 16-20 on the summit of Shiva's Temple in the Grand Canyon, Arizona (see NATURE, Sept. 25, p. 537). Some seventy-five specimens, it is stated in the report in *The Times* of September 30, were shot or trapped, and will be forwarded to New York for examination. They include chipmunks, three or four species of mice, cottontail rabbits, rock squirrels, which resemble the common grey squirrel, and pack rats, of which one species may be peculiar to Shiva's Temple. As regards the problem whether isolation has produced any marked changes in appearance and habits, Dr. Anthony is of opinion that the colour of the specimens as a whole is lighter than that of those on the north and south rims of the Canyon, respectively one and a half miles and eight miles away in a straight line; but confirmation by detailed comparison is awaited. The vegetation, consisting of pines, junipers, shrubs, and cactus, is described as "more arid" than that of the mainland, and the heat as greater. The plateau, it is stated, is evidently visited in winter by cougar, or mountain lion, and coyote. As the report refers to the discovery of many Indian remains in the shape of mounds, ovens and tools, presumably the members of the expedition were not the only visitors to reach the summit since its isolation from the mainland, as was claimed originally, and the expectation of evidence bearing on the high antiquity of man in this region seems doomed to disappointment. Nevertheless, it is to be concluded that the remains are 'early', and any material which affords evidence of cultural or racial succession in the south-western States is of importance, especially in the present state of knowledge. It may be hoped that an opportunity will be found to submit the material *in situ* to careful and expert examination.

Broadcasting in India

AN outline of the policy and plans of the broadcasting organization known as All India Radio for the erection of broadcasting stations in India was given in a recent issue of the *Indian Listener*. The two main features of the problem of providing a broadcasting service in India are the relatively large area of country to be covered, and the intense atmospheric interference. It is considered to be desirable to provide as quickly as possible some sort of broadcasting service for the whole area of India, and with this object in view five short-wave transmitting equipments have been ordered and will be located at Delhi (two stations), Bombay, Calcutta and Madras. At the same time, five medium-wave stations have been ordered to provide a first-grade broadcasting service for the towns of Lahore, Lucknow, Trichinopoly, Dacca and Madras. These will supplement the existing medium-wave stations at Delhi, Bombay, Calcutta and Peshawar, so that shortly All-India Radio will have in operation five short-wave and nine medium-wave stations, the aerial power ratings of these varying from 0.25 to 10 kw. Bearing in mind that, in contrast with the practice in other countries, the short-wave stations have to provide an internal service in India, the operating wave-lengths will probably be between 30 and 50 metres for daytime and between 60 and 90 metres for night working. It is considered unlikely that there will be any interference between these stations working an internal service in India, and European and other short-wave stations operating an international service. The new medium-wave stations will operate on wave-lengths between 200 and 400 metres and will have large frequency separation so as to facilitate the provision of simple cheap receivers.

At the present time the position with regard to broadcasting receivers in India is unsatisfactory owing to their high cost. It is considered that with the development of transmitting stations now being undertaken, there will shortly be room for three types of receiver. The first is a cheap, popular receiver suitable for local reception from the medium-wave stations. Next comes the "All-India" receiver suitable for receiving all the stations now in contemplation, and thus capable of covering the short-wave band of 30-100 metres as well as the normal medium-wave band of 200-550 metres. The third type of receiver is in the "all-wave" class generally available at the present time in Great Britain, except that it should cover wave-lengths from 13 to 100 metres without a gap. In addition, there is a demand in India for wireless receivers suitable for community reception in villages, and the Research Department of All-India Radio has already developed a special set for this purpose. No external controls are provided on this receiver, which is left tuned to the local station and is operated by a clockwork time-switch, which turns the receiver on and off at the correct time for the "village hour". The only attention required by these receivers is a visit once every three weeks to change the accumulator battery and re-wind the clock.

Origins of Clerk Maxwell's Electric Ideas

A book entitled "Origins of Clerk Maxwell's Electric Ideas as described in Familiar Letters to William Thomson" has been published by the Cambridge University Press (price 3s. 6d.). These letters cover the period 1854-79 and illustrate clearly the genesis and rapid progress of Clerk Maxwell's ideas as he groped his way towards a structural theory of the electric and magnetic field. Some of the questions he asks Thomson are by no means easy to answer. In his first letter (Feb. 1854) he asks: "Suppose a man to have a popular knowledge of electrical show experiments and a little antipathy to Murphy's Electricity, how ought he to proceed in reading and working so as to get a little insight into the subject which may be of use to him in further reading?" In subsequent letters he continues to ask still more intricate questions, so doubtless Thomson's answers must have been satisfactory. In another letter he says, "I do not know the game laws and patent laws of science . . . but I certainly intend to poach among your electrical images". He fully appreciates Thomson's problem of an electrified spherical bowl. "Your bowl investigations are first-rate. I must find the induction through a round hole in a plate by means of them. Whether would you have me bag the whole thing for my book, or give results and references with an account of the method?" The letters given in this book were originally printed in Part 5 of vol. 32 of the *Proceedings of the Cambridge Philosophical Society*. As they will be of interest to many mathematical physicists, the Cambridge Press did well to publish them. Sir Joseph Larmor has edited the book.

Clean Milk and Pasteurization

DR. G. ARBOUR-STEPHENS, of 61 Walter Road, Swansea, writes, with reference to the article on the nutritive value of pasteurized milk (*NATURE*, 140, 389; 1937), that it is not justifiable to compromise a diminution of value in order to prevent the effects of handling by dirty people. Unfortunately, the problem is scarcely as simple as this: in spite of the greatest care and cleanliness in handling the milk, it cannot always be possible to prevent contamination from organisms which may have produced no obvious illness in the worker himself, but yet may be capable of producing illness in other people, or from organisms which may be disseminated during the incubation period of an infectious disease and before the symptoms have become obvious. To prevent otherwise unavoidable outbreaks of infectious diseases among the consumers of milk is the true function of pasteurization: it is certainly not to be considered as allowing the production of dirty milk, which can then be rendered innocuous before consumption. The aim should surely be the production of clean milk from disease-free herds, with pasteurization to obviate the ill-effects of any lapse in technique, which is bound to happen occasionally considering the many stages through which the milk has to pass under modern conditions before it reaches the consumer, or to prevent the accidental entry of virulent organisms.

Practical Aspects of Human Nutrition

THE text of a lecture entitled "The Place of Vegetables and Fruit in the Well-balanced Diet", which was delivered before the Royal Horticultural Society by Dr. G. E. Friend, is printed in the Society's *Journal* of July (62, 7, 286-295). A review of modern conceptions of the nutritional needs of the human body dealt principally with the quality of diet, rather than with quantity. Dr. Friend has charge of the health of the boys at Christ's Hospital; perhaps the members of this and similar closed communities may be regarded as adequate critics of palatability and other human aspects of diet. The nutritional value of fresh fruit and vegetables varies considerably, and but little is known about factors affecting variation. Emphasis is placed upon the necessity for co-ordinating human and plant nutrition. The best way of ensuring qualitative adequacy of protective vegetable foods is to begin with their cultivation. Soil conditions must be suitable for the production of sufficient amounts of vitamins and the minor essential elements necessary for human nutrition. Such high-grade vegetables naturally cost more to grow, and one of the problems of the future will be to convince those who hold the economic control of diet of the value of such improved produce.

The Tobacco Problem

IN an address on this subject before the Southampton Medical Society on October 6, Dr. J. D. Rolleston maintained that the tobacco habit is quite as much a concern of public health as that of acute infectious disease, a view which appears to be gaining ground in Germany, where many members of the public health service are of opinion that the harm done by nicotine is as great as that caused by alcohol. In Great Britain, however, apart from the Society for the Study of Inebriety and Drug Addiction, there has been little discussion in scientific meetings of the tobacco problem, like until recently any aspects of the sexual question. In a survey of the action of tobacco on the various systems of the body, Dr. Rolleston remarked that though in most cases little harm is likely to ensue from a mild degree of smoking, some smokers, even those of long standing, are liable to develop toxic symptoms after only a small amount of tobacco, while a considerable proportion of all tobacco consumers smoke to excess. Other subjects discussed in the address were the incidence of smoking in different countries, the relation of tobacco to cancer of the upper respiratory and alimentary tracts, tobacco in training, smoking in hospital wards, the occurrence of extensive fires due to smokers' carelessness and the formation in 1926 of the National Society of Non-Smokers.

A Philosophical Overhaul

WE have received the first chapter of a book entitled *A "Philosophical Overhaul"* by Oscar Ljungström, printed in English by H. Ohlsson of Lund. It is a well-written philosophical disquisition on such subjects as force, gravitation, chance, free will, causation, time, etc. It is most readable and forces one to think. The author begins "A philo-

sopher is a doubtful man, and he puts all kinds of unnecessary questions. Not like Socrates in the forenoon, to the citizens of his own town. For if he did that nowadays they would probably turn him out with the American injunction: 'If you have nothing to do, don't do it here'. So it is safest for him to keep his doubts within his own soul, murmuring some answers to himself." The questioner has contracted the habit of writing books, and so he gives the first chapter of a proposed book. He suggests that gravitation may be explained by cosmic radiation and that time cannot be measured at all. He has the merit of not being dogmatic and his suggestions are interesting and put forward modestly.

A Business Man's Library

A SELECTED list of books under the heading "A Business Man's Library" compiled by the Management Library has been issued by the National Book Council, 3 Henrietta Street, Covent Garden, London, W.C.2, from which copies may be obtained. The list covers purchasing, factory management, personnel and industrial psychology, sales management, market research, advertising, transport, general management, accountancy and statistics, commercial law, industrial biography and industrial history. While not exhaustive, it includes most of the significant recent additions to the literature of this field and is a useful adjunct to the more comprehensive "Business Man's Guide to Management", the fifth edition of which has just been published by the Management Library (23 Bloomsbury Square, W.C.1). In addition to the classified lists of books, with brief descriptive notes on their scope or contents, the latter contains a subject index, a publisher index and an author index as well as suggested courses of reading. Reference to the main divisions, general management, accounting, production, distribution, company secretary, psychology, industrial economics, in which the books are listed is facilitated by use of different coloured paper for these divisions.

Library of the American Philosophical Society

THE report on the library of the American Philosophical Society for 1936 includes details of the more important additions (Philadelphia: American Philosophical Society). Among the new exchanges of publications established during the year is one with the library of Armstrong College, Newcastle-on-Tyne. At the end of the year the Library contained 80,918 volumes, 48,468 pamphlets and 5,374 maps. The Library does not attempt to develop all fields of learning, but only those in which it is already strong or has historic interest. No expansion in modern books on medicine is contemplated owing to the existence in Philadelphia of a very important medical library, but fields in which development is intended include exploration; botany, scientific and applied; the history of science; the inter-relation of the sciences; the co-operation of learned societies and institutions. Further contributions have been made to the promotion of the Union Catalogue of Philadelphia, and the report includes a summary list of archival materials in the possession of the Library,

the most important of which is the collection of Franklin manuscripts. Much work has been carried out in preparation for the issue of a descriptive catalogue of these manuscript collections.

Smithsonian Publications

A CLASSIFIED list of Smithsonian Publications, available for distribution, August 10, 1937, compiled by Helen Monroe, has been published by the Smithsonian Institution, Washington (Publication 3394). The papers are supplied only as an aid to researches or studies in which the applicant is specially interested, and accordingly applicants are required to state the grounds for their request. Except where prices are given in the list, the papers are distributed gratis. The serial publications of the Smithsonian Institution are of three types: Smithsonian Contributions to Knowledge; Smithsonian Collections; Smithsonian Annual Reports. The reports are distributed gratuitously to libraries and individuals throughout the world, but very few are now available at the Institution. The papers issued in the Contributions to Knowledge and Miscellaneous Collections are not public documents but are printed in limited editions and distributed without charge to public libraries, educational institutions and learned societies. They are supplied to other institutions and to individuals at the prices indicated.

Calendar of Chemistry

AN interesting list of names and dates has been drawn up by E. H. Huntress with the title: "Daily Chemical Anniversaries as a Teaching Tool", published in the *Journal of Chemical Education* (14, 328; 1937; obtainable in reprint form at a small charge). In this, each day of the year is assigned to some names of investigators distinguished for their contributions to chemistry and related sciences, who were born on that day in a year specified. The date of death is also given when the person is no longer living. In this way a valuable historical document has been produced, and it is clear from the brief introduction by the author that he has taken a great deal of trouble in collecting his material from reliable sources and in converting the dates based on different calendars to the Gregorian basis. He suggests that the list can be made use of in teaching, and it certainly offers interesting possibilities in this direction.

Game Research

APART from a few special investigations, such as that on grouse disease, little persistent attempt has been made to study the diseases of game or methods of controlling disease or increasing the health and productivity of game. The opening a few years ago of a game research estate at Knebworth by Imperial Chemical Industries Ltd. was therefore a movement of scientific as well as of sporting interest, and now a second centre has been set up at Jealott's Hill, Warfield, Berkshire, for the study of problems relating to intensive rearing and the incidence of disease. From these stations appear occasional short pamphlets dealing with the progress of research or

summarizing present knowledge regarding specific diseases. Advisory Leaflet No. 12 (June 1937) deals with a few diseases of game most commonly encountered on rearing-fields and amongst wild stock, and offers some suggestions for simple treatment such as a keeper could apply. The diseases referred to are gapes, coccidiosis, cramp, pneumonia, 'sore mouth', and strongylosis or 'partridge disease'.

Partridge Mortality

THE question of "Partridge Stocks and Mortalities" is discussed in I.O.I. Game Researches, Advisory Leaflet 13, June 1937. The pamphlet is based upon information gathered from a large number of partridge manors throughout Great Britain and analysed by A. D. Middleton, of the Bureau of Animal Population. The matters discussed include losses of nests, fertility of eggs, mortality in young partridges, stock estimates, winter wastage, mortality and its reduction. The pamphlet is simply written and should be a useful guide to the shooting man and his keeper—to whom the original papers are not likely to be available—as to what may be expected amongst a normal stock of wild partridges.

Bibliography of Seismology

THE recent quarterly part of the "Bibliography of Seismology", edited by Mr. Ernest A. Hodgson, concludes the record for the year 1936 (*Pub. Dominion Observatory, Ottawa*, 12, 1936-37). The value of the work will be evident from the fact that the number of entries for the year is 429. To a great extent, the practice of adding notes on, or abstracts of, the memoirs is abandoned. On the other hand, the useful plan of giving references to notes or articles in various scientific journals—such as *NATURE*, *Science*, etc., and the *Proceedings* of such bodies as the Academy of Sciences of the U.S.S.R., the Geodetic Survey of India and the Society of Petroleum Geophysicists—is extended. The countries in which earthquakes are studied are now so well represented on the list of contributors that few, if any, memoirs of importance can escape notice. The last number contains a useful subject-index under more than fifty headings.

An Active Sunspot

A LARGE and active group of sunspots, visible to the naked eye, is in transit across the sun's disk (September 28–October 11) in latitude 10° N. The date of central meridian passage was October 4.6. The following measures of area made at Greenwich and expressed in millionths of the sun's hemisphere illustrate the rapid growth of the group from September 28, when it was seen coming into view at the sun's east limb:

Sept 28 44	Area 450
" 29 3	" 1100
" 30 4	" 1700
Oct 1 3	" 2100
" 4 4	" 3100

By October 1, a number of separate nuclei had developed into one very long complex spot.

Scientific Endeavour and Inferiority Complex

Recollections of My Life

By Santiago Ramón y Cajal. Translated by Prof. E. Horne Craigie, with the assistance of Prof. Juan Cano. (*Memoirs of the American Philosophical Society*, Vol. 8, Parts 1 and 2.) Part 1. Pp. xi+272+13 plates. Part 2. Pp. ii+273-638+plates 14-21. (Philadelphia: American Philosophical Society; London: Oxford University Press, 1937.) 22s. 6d. net.

IT is a pleasure to greet this work in an English dress. The Spanish original appeared in Madrid in 1923. A personal document, at once historical and self-revealing, it went through three editions before its author's death in 1934. For it to be accessible to a larger audience has been a desideratum for some years.

Among autobiographies of scientific men this seems likely to occupy permanently an outstanding place. It presents features, and attaches to circumstances, of exceptional interest. It comes from the pen of one who was not only a great master in his branch of science but was also a personality of rare attraction. It deals with the story of a time pregnant with change and revulsion from old ways in the writer's own country. It tells this story from its particular angle the more effectively by reason of a certain detachment from the political field, a detachment based on loftiness of view rather than on any lack of passion for his country's cause.

The microscopist on the whole is, we may think, at some disadvantage for facts in his career which shall enlist general or public interest. He has not the romance of being armed with a gigantic instrument exploring spaces and systems which by their mere enumeration leave thought staggered. His life is perforce a sedentary one with little opening for adventure. Moreover, even with the microscope, Cajal's scope of observation lay in

a field not containing such exciting things as the seeds of new diseases or the specks identified as carriers of particulate heredity. It was on no such grounds as those that these "Recollections of My Life" have justified their writing. As to Cajal's scientific work, it is not always the discoverer himself who can best set forth to a lay world the broad meaning of what he has discovered. Nor do we think Cajal excels in that particular respect. Yet the book succeeds in presenting his scientific work clearly and well, though not with much gift of popular exposition. His achievement was not of a kind made easily the subject of spectacular appeal. It introduced, however, a new conception of the structure of the nervous system in its entirety and throughout.

It is probably true to say that no single observer ever yet so enlarged our knowledge of the construction of that system. His fresh conception of the structure carried with it unusually unequivocal inferences regarding certain fundamental features of its working. For physiologist and pathologist, the nervous system after Cajal's discoveries and interpretation was something so much clearer and so other than it had been as to be a system almost new, and one immensely more intelligible. That was a revolution dramatic enough to those observers technically facing the problem. But to those not so specially acquainted with it, its very technicality stood in the way of the investment of it with great general interest. The work before us has therefore, we think prudently, curtailed some of the scientific summaries and discussion, and dispenses with some of the scientific illustrations. Those parts of the work which are its truer sources of appeal and value are thus assisted rather than impaired.

One of the permanent sources of appeal in this unrestrained autobiography—for such it is—is its

frequent half-naïve, but never gratingly egotistical, resort to and exposition of its author's own views on human life and character in general, his own instance being commonly their text. These thoughts are often strikingly unsophisticated, the very reference to them somewhat of a departure from convention. At times this, like magic, turns a slight circumstance into a memorable and arresting passage for the reader. It is surely a prerogative of the Latin genius little permitted or possible to what goes by the name of Anglo-Saxon. It must have presented especial difficulty for this translation of the book. Prof. Horne Craigie has, we think, dealt with it in the best way possible. "So much of the personality of an author is contained in his very diction and phraseology, that it was felt best to risk sacrificing to some extent the values of literary English in order to try to give as precise rendition as possible of each word or phrase of the original". The reader finds that this has been done with exemplary care. In result a trace of exotic character tends to attach to the text in many places, and to our thinking harmonizes with it, because it seems in keeping with something exotic to us in the author's sentiment.

One interest of the book is, and will probably for a long time increasingly be, the writer's picture of Spain, the position science and scientific medicine held there, and their social and quasi-political contacts in Spain during the writer's long career. Light is shed on, for one thing, an inefficiency of educational organization for science such as, whatever be the issue of the present conflict in Spain, can, so long as this book speaks, never return. The book is a self-portrayal of a heroic figure striving to regenerate his country's science and, as regards science, his country's faith in itself. It is a portrayal undertaken without vanity, and in its way free from self-consciousness. It raises before us a figure which might well serve as a symbol for a future Spain cultivating scientific achievement. We get a picture of the devoted effort of a few to re-establish in their country the cult of scientific knowledge for its own sake. The struggle depicted was against not so much any organized opposition from creed or class as against apathy under a starved educational system. Further, the national conscience had come ruefully to consent to believe that in natural science Spain was no longer to be taken seriously. An inferiority complex in respect of science sapped the nation's strength and initiative. Cajal's own contributions to research called forth from his university colleagues the remark "who is our Cajal to judge of foreign scientists!" "So deep in the vitals of our race had taken root the conviction of our sad and utter incapacity for the cultivation of Science."

Another stumbling-block for Spain, as her great master here points out, was her own language. It invests with a certain pathos some valedictory words he addressed to the young scientific Spain he had created. "One of the urgent tasks our young investigators will have is the translation into English, French or German of the essential facts discovered in our country." He had in 1897 at no small pecuniary sacrifice started a Spanish quarterly of microscopy. This with the opening of the new century became the famous *Trabajos*. But after a quarter of a century's trial he felt forced to change the title into French and to "publish the work of our laboratory in French or English". His experience was that otherwise it did not reach the scientific world; "a bitter reflection," he remarks.

Cajal had consented to be Minister of Education under a prospective term of one of the Liberal Governments. Partly at his own later request that did not come to pass. But the volume is full of reflections upon education in general and the public organization of education in Spain in particular. It is rich in reminiscence illustrating the system as it existed; he watched it in school, college and university. He lived through a period which, largely by his own example and exertion, was in some respects one of great transition. For those historians to whom the phases of history of most interest are the phases of transition, Cajal's volume provides a valuable original source. As a young student he heard vitalistic doctrines taught direct from Borden and the Montpellier School of the eighteenth century. Some ten years later he was facing cholera with pure cultures of the 'bacillus' and an oil-immersion lens; and he lived to find himself in a palatial laboratory abreast of the latest in the world in respect of the particular study he had made his own.

Bits of the "Recollections" were rendered into English some years ago by the accomplished medical historian Fielding Garrison, now passed away. He recognized a vein of poetry in some of Cajal's writings. It is present in this book, and with it a vein of melancholy—without that bitterness which stings in some of the aphorisms of the "Charles de Café"—also in part at least translated by Garrison. An instance of the melancholy—and the poetical—is a passage in the last chapter of these "Recollections". Its subject is the scientific master whom old age is gripping—in fact himself at the time of his writing it. Unconsciously it challenges, by contrast, Browning's picture of Linares in "A Grammarian's Funeral". It says, too, what Mr. Aldous Huxley, in the memorial lecture on his grandfather, said of the fate of scientific writing—but says it with a wistfulness of regret. "It is certain and even desirable

that in the course of time my insignificant personality will be forgotten; with it will doubtless perish many of my ideas. In spite of all the blandishments of self-love, the facts associated at first with the name of a particular man end by being anonymous, lost for ever in the ocean of Universal Science. The monograph impregnated with individual human quality becomes incorporated, stripped of sentiments, in the abstract doctrine of the general treatise. To the hot sun of actuality will succeed the cold beams

of the history of learning." We may express this in short by saying that, as Aristotle thought of the soul, a scientific writing has no personal immortality. Yet this book will, we fancy, long have its place on the library's 'international shelf'.

Prof. Horne Craigie is to be congratulated on his work. The volume is well produced. There are a few misprints, for example, on pp. 303, 327 and 531. The book meets a distinct need.

C. S. S.

Primitive Art and Artists

The Savage Hits Back:

or The White Man through Native Eyes. By Prof. Julius E. Lips. Translated from the German by Vincent Benson. Pp. xxxi + 254. (London: Lovat Dickson, Ltd., 1937.) 21s. net.

AFTER this book had been written and was passing through the press, Prof. Julius E. Lips, formerly director of the Rautenstrauch-Joest Museum of Cologne, was moved to tell his readers in a foreword the circumstances of its production. Although not a Jew, his championship of freedom of thought and research brought him into conflict with the authorities and cost him his appointment. When deprived of all opportunity to continue his work and summoned to deliver up the material, which he had collected laboriously for the purpose of investigating this particular manifestation of primitive art, on the ground that it was subversive of the Nazi doctrine of Aryan supremacy—it certainly does not flatter the white man—he left his country to take refuge in Paris and later in America.

This prelude may seem irrelevant to the purpose of a study of a form of art; but it is a story which is fittingly told here. It literally shocks us into an appreciation of the fact that such masterpieces of expression and critical characterization as are shown could be produced only in an atmosphere of emotional and intellectual freedom removed *totò còlo* from the suspicions and repressions of a totalitarian regime. The advantage lies entirely with the savage.

Prof. Lips had brought together, classified, and analysed a large number of examples of primitive art in which the artist embodied his impressions of the white men with whom he has come into contact, and also of some, though indeed not many, of the white women, as well as his conception of his distant rulers in Europe. Of these a selection is figured and discussed in this volume. Most of them, though not all, are sculptures in

wood, ivory and other material. They are drawn from a wide field—Africa, Australia, Melanesia and New Guinea, the Eskimo and the Indian of the North-West Coast and South America. In time they range from the sixteenth century bronze and ivory figures of Benin art down to the present age of the motor-car. Some of the best belong to the nineteenth century. Generally, the art of the higher cultures, such as India, Japan and China, has been omitted from consideration, although some work of the Chinese has been included for purposes of comparison—a severe test, from which the primitive emerges not without credit.

When they are considered without reference to the author's purpose, these examples of primitive art are seen to attain a high standard. So far as technique and execution are concerned, they serve to illustrate the author's brief but excellent dissertation on the principles and conditions of primitive art. This dissertation, however, is more or less by way of necessary introduction to the main theme. Of the abilities of the primitive artist in his representation of that strange and in many ways mysterious being, the white man, the most striking characteristic brought out in the examples shown here is that only rarely, if at all, has there been any failure to catch and express the national particularities of the model. Englishman, Frenchman, German, Russian, whatever he may be, it is impossible to mistake what the artist intended to represent—and the likeness is more than superficial, it is a portrayal of the spirit. Here, as always, African art excels, perhaps most because of its deep-seated humour and its genius for exaggerated characterization, amounting at times to caricature. In contrast, Prof. Lips maintains that before Gauguin no European artist, with one exception, had succeeded in representing the primitive; while in travel books before the photograph, representations of natives were no more than Europeans sometimes, but not always,

decked out in the appropriate native costume and ornament. This sweeping statement is something of an exaggeration; but it has much to support it. In these examples of African art, however, there can be no question; and English officer, French officer, native soldiery, missionary, trader, and even the English female tourist are touched off to the life. Africa, however, has no monopoly. Russian figures from the North-West Coast are no less successful, and the masks of massacred sailors or traders from New Ireland are distressingly true to fact.

Prof. Lips, in discussing the principles which govern the approach to the study of primitive art, emphasizes the fact that such an art can exist only as a manifestation of, and in relation to, a specific culture. Incidentally, in characterizing a certain school of modern sculpture as purely African, he provides both a condemnation and a refutation of aesthetic theories which ignore the anthropological point of view. When, however, he goes on to deplore the inevitable disappearance of primitive art, as do other writers on African

art for example, he is guilty, may it be said with all due respect, of a certain confusion of thought. His material must surely demonstrate this. The primitive cultures which produced it had already undergone modification by European contacts. The art, in consequence, had suffered some change, but it had neither deteriorated nor perished. Provided that it can be ensured that change in culture is organic, as for example is the aim of 'indirect rule', and not disruptive, but follows lines of development inherent in native custom and institutions, there is no reason why the capacity for artistic expression should not develop likewise, provided it is not disturbed and crippled by the introduction of alien European ideas, principles and technique. This, at least, would seem to be the lesson of the experimental introduction of native craftsmen as teachers at Achimota.

Finally, it may be said that this is a book which no student of social anthropology can afford to neglect. Apart from the light it throws on primitive art and artists, it is an illuminating study of the ways of thought of the primitive mind.

The Distribution of Animals

(1) Ecological Animal Geography

An authorized, rewritten edition based on "Tiergeographie auf ökologischer Grundlage" by Prof. Richard Heese. Prepared by W. C. Allee and Karl P. Schmidt. Pp. xiv + 597. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1937.) 30s. net.

(2) Animal Communities in Temperate America: as illustrated in the Chicago Region—a Study in Animal Ecology. By Victor E. Shelford. (Geographic Society of Chicago, Bulletin No. 5.) Second edition. Pp. xiii + 368. (Chicago: University of Chicago Press; London: Cambridge University Press, 1937.) 13s. 6d. net.

DURING the present century, the study of the distribution of animals has entered upon a new phase, marked by a more intense examination of the relationship between animals and their environment, and a desire to bring to the understanding of distribution a physiological point of view applied to communities as well as to individual species and systematic groups. As regards land animals the older works, of Murray, Wallace, Heilprin, Trouessart, Beddard, Lydekker, Selater and others, were based largely upon the knowledge of mammals and birds, and these warm-blooded animals were less obviously subject to several climatic factors which regulate the distribution of less specialized animals; whereas, as regards

marine organisms, from the time of Edward Forbes, the tendency had been to accumulate data of distribution with reference to 'zones' or other generalized areas.

The development of ecology has given a new complexion to the understanding of distribution, and although in this respect the zoologist has lagged behind the botanist, the works noticed here have consolidated the position and placed the zoologist in line for further advances.

(1) Prof. Richard Heese's "Tiergeographie" set a new standard, with its appeal to modern methods and its weighty accumulation of examples widely drawn from zoological research papers. There has been no English work quite like it, although the posthumous volume of Dr. Marion I. Newbigin, "Plant and Animal Geography" (1936), discussed ably and in a rather less minute way some of its main topics. Since the publication of the "Tiergeographie" in 1924, however, much has been done, and the translators and joint-authors, realizing that a transcript would no longer meet the needs, have with Prof. Heese's concurrence placed their own stamp very thoroughly upon the work. They have used their own experience and reading to revise and add, have deleted material with which they did not agree—for example, Lamarckian interpretations stuck in their gorge and were rejected—and they have increased the emphasis upon the influence of marked climatic

variations during the world's history and upon the stability of the present ocean basins. The chapter on the influence of man upon animals has been rewritten, mainly from an American point of view, and the text has been made more readable by the weeding out of Hesse's plethora of scientific names and the simplification of the scientific references. The result is a first-rate work, containing much widely gathered information, and suggesting many problems for the ecologist.

Since the original book was not reviewed in NATURE, its scope may be indicated. The greater part, in three sections comprising nineteen chapters, discusses the actual distribution of animals, in the sea (138 pp.), in inland waters (89 pp.), and on the land (180 pp.). In each case the discussion leads off with an account of the environmental factors and of their relation to animal life, and this is followed by more detailed accounts of the various communities and their structural and physiological relations to the natural conditions in which they live. Preceding these descriptive sections is a valuable introductory section of nine chapters (149 pp.) setting out the general problems and relations of ecological animal geography.

The difficulty about biological generalizations is that exceptions so often threaten to break the rule; in other words, the factors are so complicated that clear cases seldom occur. Here the familiar zoogeographical regions of the earth's surface are condemned as abstractions, because transition areas transgress their supposed objective boundaries; but the positive conclusion is the more helpful, namely, that "the faunal regions are divisions of the earth's surface in which the animal life bears a somewhat uniform aspect, and differs from that of the neighbouring regions in consequence of independent evolution during longer or shorter periods of isolation". When the authors, in support of Bergmann's rule that when the same species inhabits different climates the individuals tend to attain the greatest size in the coolest regions, cite (amongst others) the case of the red-deer as increasing in size towards the north-east of Europe and decreasing towards the south-west, they seem to lean upon a weak reed, for the Norwegian specimens are less than the Swedish, and both are inferior to the deer of Germany and the Carpathians; perhaps the factor of food upsets the rule. Also, how are we to account for the fact that the distinctive forms of the sea-girt St. Kilda (oceanic climate), whether they be field-mice or house-mice or wrens, are larger than their fellows on the Scottish mainland? It is an interesting thesis, supported by many examples and accounted for in various ways, that the extent of a region is reflected directly in the numbers of its species and even in their size.

In regard to the major facts of historical geography, the authors dismiss Wegener's theory of continental drift in a sentence; but since the 1928 symposium which they follow, geologists have been weakening in their opposition, and the remarkable parallels drawn by du Toit between the geological formations of South America and South Africa suggest that zoologists should for the present keep an open mind.

In the bibliographies the translators have included many important works published since 1924, but admitting that rigid selection was necessary, reference might usefully have been made to C. B. Williams's "Migration of Butterflies" (1930) in connexion with the movements of insects, to Taussig's important "Ökologische Haustiergeographie" (1932), and in connexion with inland waters to Murray and Pullar's six-volume "Bathymetrical Survey of Scottish Fresh-water Lochs" (1910), and Hora's accounts of the adaptations of animals in rapidly running streams.

The book is well printed, is illustrated by instructive and modern text-figures (although there is a wretched photograph of the gannets on the Bass Rock), and is very free from slips ("save" for have, p. 117, l. 31; "Agric." for Avic.; p. 418 ref. 10; and the misleading "Baltic starfish" given as the English name for the four-bearded rockling).

Most of these points are matters of opinion, but there can be no two opinions about the value of the book itself.

(2) Shelford's "Animal Communities" has been for so many years an indispensable guide in the teaching of ecology in Great Britain that its merits do not require to be stressed. The second edition is an impression of the first, unchanged except for the correction of typographical and clerical errors, the modification of community nomenclature, and the addition of a short bibliographical appendix. But the advances of animal ecology since the original work appeared in 1912 make it odd to read the complaint that zoology has furnished geography only with data almost exclusively concerning the taxonomy and morphology of animals (p. 318); Hesse (not mentioned in the bibliography) and his cloud of witnesses are the answer. In the first chapter (where "Thompson" (p. 6) should be Thomson), the section on "the economic importance of animals" contains no reference to domestication.

However, the body of this pioneer work, a descriptive account of typical habitats and their communities, with occasional suggestions of the changes which both may undergo in parallel, retains its original value as an introduction to the modern method of field natural history.

JAMES RITCHIE

Communal Life Among Termites

The Soul of the White Ant

By Eugène N. Marais. With a Biographical Note by his Son and translated by Winifred de Kok. Pp. xv+184+8 plates. (London: Methuen and Co., Ltd., 1937.) 7s. 6d. net.

THIS book is of considerable interest; it contains a number of original observations and there are some good plates and text figures. The original was written in Afrikaans and the translation is by Winifred de Kok.

The translator, in her preface, writes: "His years of unceasing work on the veld led Eugène Marais to formulate his theory that the individual nest of the termites is similar in every respect to the organism of an animal, workers and soldiers resembling red and white blood corpuscles, the fungus gardens the digestive organs, the queen functioning as the brain, and the sexual flight being in every respect analogous to the escape of spermatozoa and ova.

"About six years after these articles appeared (his original papers) Maurice Maeterlinck published his book "The Life of the White Ant", in which he describes this organic unity of the termitary and compares it with the human body. This theory aroused great interest at the time and was generally accepted as an original one formulated by Maeterlinck."

Marais further classes the workers as the mouth and teeth and the soldiers as the functional equivalent of the medulla oblongata; the fungus gardens as the stomach and liver, and the termitary itself as not a heap of dead earth, but as a separate animal at a certain stage of development—a composite animal in exactly the same way that man is a separate composite animal, only without the power of locomotion. By the operation of natural selection the final result will be a termitary which moves slowly over the veld! We fear we have not sufficient imagination to conjure up such a miracle. Such a theory would naturally appeal to the poetical mind of Maeterlinck; but he should at least have given Marais the credit for it.

It appears to us that the author in his endeavour to prove his theory over-reached himself, and probably thereby lost sight of a number of equally interesting facts and problems. We have seen it stated that if his facts are beyond question his theory is quite unanswerable. We do not agree with this statement; but at the same time we propose to show that in many instances what he says is incorrect.

The theory itself is only a poetical invention and gets one nowhere. One might equally well compare the termitary to the heavenly bodies, the queen being the sun, etc., and use similar arguments to try to prove it. The statement that the king and queen are ordinary four-winged *neuropterous* insects is contrary to what is known on the subject. Termites are now considered to be descended from a common ancestor to that of cockroaches, and possess some characters similar to those insects.

The queen is said by Marais to have the power of producing three different forms of insects: the queen, the worker, the soldier. As a matter of fact she can produce, as shown by Wheeler, sixteen different kinds of individuals, as follows: first-form males and females (true kings and queens); second-form males and females; third-form males and females; large male and female workers; small male and female workers; large male and female soldiers; medium-sized male and female soldiers; small male and female soldiers.

It is probable that not all these occur at once in one colony, but five or six are often to be met with in a single colony.

It is stated that all direct activity ceases in the termitary immediately the queen is destroyed, and there is an end to the community as such.

This may be the case in a small new termitary, but certainly not in a large old one. The second- and third-form adults are complementary or substitutable kings and queens, and can be used if, or when, the true queen (or king) dies. The second form have wing pads or incipient wings and perfectly formed reproductive organs, though smaller than in the first form, and the third form are entirely wingless, but possess mature reproductive organs which are smaller than in the second form.

The author says of the true kings and queens that one moment the insect is flying, a moment later the wings are detached, yet one finds no evidence of a lesion. Wheeler points out that the wings of the first-form adults break off at pre-formed basal sutures, and old individuals of this caste can always be recognized by the truncated wing-stubs. Marais also mentions wing-buds being sometimes present, but attributes this to atavism.

Many other instances might be brought forward, but the space at our disposal will not permit. It must be remembered that the habits of different species of termites (as with ants) differ, and the author was only observing one species.

HORACE DONISTHORPE.

Amenities of the Countryside

(1) *England under Trust:*

the Principal Properties held by the National Trust in England and Wales. Described and illustrated by J. Dixon-Scott. Pp. xx + 339 + 62 plates. (London: Alexander Maclehose and Co., 1937.) 7s. 6d. net.

(2) *Britain and the Beast*

By J. M. Keynes, H. J. Massingham, Sheila Kaye-Smith, E. M. Forster, W. A. Eden, O. E. M. Joad, John Moore, Clough Williams-Ellis, Geoffrey M. Bompfrey, R. G. Stapledon, A. G. Street, Patrick Abercrombie, Thomas Sharp, G. O. Hines, Howard Marshall, Lord Horder of Ashford, G. M. Trevelyan, John Gloag, Sir William Beach Thomas, S. P. B. Mais, R. M. Lockley, Kenneth Spence, Edmund Vale, George Scott-Moncrieff, Lord Howard of Penrith, Aileen Tatton Brown. Pp. xx + 332 + 41 plates. (London: J. M. Dent and Sons, Ltd., 1937.) 10s. 6d. net.

THE almost simultaneous publication of these two books marks an important stage in the increasing consciousness of Englishmen that they have in their countryside and their older buildings a historic heritage of incalculable value which is in danger of destruction and ought to be made secure for the enjoyment and education of their descendants. One of them is a pictorial and descriptive account of the principal properties held by the National Trust and is thus primarily a record of achievement: the other contains the views of twenty-six eminent persons on various aspects of the problem, some being content to describe, and generally to deplore, the present situation, while others put forward suggestions more or less comprehensive and more or less practical, which they would like to see adopted in a future policy.

(1) "*England under Trust*" contains accounts of more than fifty properties now held by the National Trust. They range geographically from Cornwall to the Roman Wall in Northumberland, and from Kent to the Lake District: in area they may be as small as Coleridge's Cottage at Nether Stowey, or as extensive as the seven thousand acres of the Holnicote Estate in Somerset. They include properties of every description—ranges of cliffs in Cornwall, an ancient hostelry in Southwark, great stretches of moorland and fell in the Lake District, historic houses like Bodiam, Tattersall, or Montacute, a complete village in Buckinghamshire, and six hundred acres of Cambridgeshire Fens.

A most encouraging feature of the record is that the Trust seems to be accumulating properties

at a rate which is rapidly increasing: the number of acquisitions here illustrated which have come into its hands since 1930 is surprisingly large. It is also interesting to note that while Cornwall and the south-west generally seem to vie with the Lake District as the areas in which the Trust has been most successful in its aims, Norfolk, Yorkshire, and the north-east as a whole seem to be still almost untouched by its activities. Another fact which emerges is that the Trust now holds a considerable number of the few remaining ancient village clergy-houses; of these, the Alfriston parsonage is probably the best known, but the church houses of Widdecombe, Muchelney, and West Wycombe are all delightful buildings.

The most valuable feature of the book lies in the magnificent series of photographs by Mr. J. Dixon-Scott: every property described is illustrated by at least one of these, and both in composition and reproduction they could scarcely be bettered. It is a pity that the descriptive notes are not up to the standard of the illustrations: they are pleasantly written on the whole, but elementary grammatical errors can be found by the curious on pp. 81, 113, 147, 189, 197, 227, and 228; and it is somewhat disconcerting to find elementary historical errors also in a book the scholarship of which Prof. G. M. Trevelyan has specially commended in his foreword. The Antonine Wall, for example, was not built by Agricola (p. 24): nor did Boudicca sack Lincoln and York (p. 187), though she did sack London, which according to Mr. Dixon-Scott escaped her: nor did the Black Prince live in the fifteenth century (p. 208). In the account of Tintagel there is no mention of Mr. Radford's recent and very important excavations, which have illuminated its history far better than the shadowy Arthurian connexions, here detailed without a suggestion of doubt on their historicity. One would have hoped that a book issued under the auspices of what is after all the National Trust for Places of Historic Interest would have paid more regard to the claims of historic accuracy.

(2) "*Britain and the Beast*" is a thoroughly depressing book, partly because it directs attention to depressing facts with which most people are familiar (although apparently not familiar enough) and partly because its twenty-six eminent authors, in spite of ten introductory pats-on-the-back from ten even more eminent persons, have nothing approaching a common policy for improving matters. Indeed the editor, Mr. Clough Williams-Ellis, has probably been wise to let each member

of his curious team have his own say in his own way, permitting no argument with his neighbours, for if anything like a symposium, in the proper sense of that abused word, had been attempted, it would probably have developed fairly quickly into a 'rough house'. Thus O. E. M. Joad's opening assumption that the primary purpose of the countryside is to provide space for townsmen to play in, is met by A. G. Street, who asserts with some asperity that it is meant for countrymen to work in. H. J. Massingham, in a survey of English agrarian history which is little better than a caricature, believes that the big landowners have ruined the rural scene; W. A. Eden, on the other hand, thinks that they are responsible for most of its loveliness. G. M. Boumphrey urges that a rigid line should be drawn between town and country, while Aileen Tatton Brown apparently contemplates an England which by 1987 has become one vast garden city.

Most of the writers seem to want the establishment of national parks, but they are far from agreed either on their location or their purpose. The individual contributions are of very varying length and, one may add, of very varying merit: some of the authors have really nothing to say,

some have a great deal too much, and some again are so choleric that it is difficult to make out whether they have any coherent ideas at all. Among those which fall into none of these classes may be mentioned W. A. Eden's sensible and constructive account of the landowner's contribution; Sheila Kaye-Smith's interesting revelations on the economics of speculative building; the editor's scheme for scheduling historic houses and their owners; P. Abercrombie's practical analysis of the deficiencies of present town and country planning legislation; K. Spence's straightforward ideas on the Lake District; and Lord Howard of Penrith's excellent account of the amenity laws in Switzerland, Germany and Sweden; while Sir W. Beach Thomas's translation of '*Littera scripta manet*' (it is very hard to get rid of printed offal) deserves a cheer all to itself.

It is a great pity that the obviously excellent photographs have been ruined by running them right over the edge of the page, leaving no margin—a modern practice which has little to commend it—and by printing them on much less satisfactory paper than is used in '*England under Trust*'. Altogether a depressing book; but that, after all, is presumably what its authors intended it to be.

The Growth of Modern Chemistry

A Hundred Years of Chemistry

By Prof. Alexander Findlay. (The Hundred Years Series.) Pp. 352. (London: Gerald Duckworth and Co., Ltd., 1937.) 15s. net.

TO write an account of the development of chemistry during the last hundred years is a task which might well daunt even the boldest spirit; for chemistry is a major science advancing rapidly on an ever-widening front, and the period in question begins not long after chemistry had become an exact science capable of mathematical interpretation. The infusion into the body of science of a new spirit—an achievement which, in Liebig's words, constituted the immortal glory of Lavoisier—led rapidly to the formulation of that comprehensive Atomic Theory the ramifications of which form the nervous system of the wonderful body of physical science as we know it to-day.

Prof. Findlay's task has been to take up the story of chemistry soon after the birth of Dalton's theory, and to trace these ramifications in a concise and intelligible manner. Such a task calls for many qualifications. Among them may be mentioned the sixth sense of the historian, the power

of critical discrimination and selection, the gift of terse expression, unending patience, a courage which never fails, and a determination to achieve the highest possible degree of accuracy. A perusal of Prof. Findlay's book will convince the most fastidious reader that the author has all these requisites.

Covering with swift strokes of his brush the limited canvas represented by some three hundred pages, our 'chymicall Artist' has produced a harmonious panorama of this century of chemistry, peopled by a rich array of pioneers of the science. As the picture grows beneath our gaze, we see how the molecular theory of Avogadro arose as an inevitable outcome of the atomic theory of Dalton; how the molecular theory called with an increasing insistence for the development of a conception of the linking of atoms into a molecular structure; and how, in turn, a body of seemingly irreconcilable facts led to the expansion of the two-dimensional organic molecular structure into a three-dimensional configuration, and thus to the birth of that vast sub-science of stereochemistry, which now embraces all substances. We see, further, how these successive advances

in theory were followed by an increasing command of practical technique, leading to the gradual elucidation of the constitution of natural products, to the synthesis of an enormous range of natural and artificial organic substances, and to the foundation of manifold industries based upon the new chemical knowledge.

Other strokes of this facile brush reveal how the determination of atomic weights led to the law of periodicity; how this law "first enabled us to perceive undiscovered elements at a distance which formerly was inaccessible to chemical vision"; how the discovery of co-ordinate families of elements indicated an identical origin; and how, as we reach the edge of the canvas, there developed from this and other sequences the idea of the electronic constitution of matter.

Our artist depicts also the spectacular developments of physical chemistry, bringing out such high-lights as the kinetic theory of gases, the correlation of physical properties and chemical constitution, the law of mass action, catalysis, the phase rule, the theory of solutions, the ionic theory . . . and, in another field of vision, the recognition and study of radioactivity, and the development of the modern theory of atomic constitution. Truly, "the records grow unceasingly, and each new grain of truth is packed, like radium, with whole worlds of light."

The value of this bird's-eye view of the growth of modern chemistry is enhanced by the copious and accurate documentation, in the form of unobtrusive footnotes. Some of these original sources have evidently been tracked down by Prof. Findlay at a considerable cost in time and labour, as they are not to be found in the ordinary books of reference. The specialist will appreciate this feature of the book as fully as the reader with a less detailed knowledge of chemistry will enjoy the easy flow of a narrative which is of necessity somewhat condensed.

As we should expect, Prof. Findlay does not neglect the human aspect of his subject, although even here, where he might have been excusably discursive, he tempers his enthusiasm with a wise restraint. He says enough to show the reader how often one investigator seems to rise upon the shoulders of another, and how narrow is the margin which sometimes divides success from failure in chemical research work. It may also be deduced that some of the figures in this historical gallery were born under a lucky star. Thus, Pasteur's first great discovery—which laid the foundations of stereochemistry—was dependent upon the fortunate choice of a specific salt, and its crystallization below a temperature of 27° C. But chance and some auspicious star have accounted for much in the history of science, as in the social and political history of nations.

Regrettably, many of these fortuitous circumstances have passed unrecorded. It is unlikely, for example, that anybody except the present reviewer knows that the first optical resolution of a substance containing no asymmetric atom in its molecule, to which Prof. Findlay refers (p. 78), was due, in the last analysis, to the dilatory habits of a certain laboratory boy, whose inaction at a critical moment has until now remained unwept, unhonoured and unsung in the records of chemistry. And certainly nobody else knows what Sir William Pope exclaimed—when the resolution had at last been effected—at the first sight of the change in the polarimeter field: suffice it to say here that he did not repeat the English equivalent of Biot's historic utterance at the first sight of the optical rotation produced by sodium ammonium laevo-tartrate: "Mon cher enfant, j'ai tant aimé les sciences dans ma vie que cela me fait battre le cœur!"

The reflective reader may well put down this book with the query, *Quo vadis?* "The ultimate components of matter," says Prof. Findlay (p. 261), "now appear to be two in number, the positively charged proton and the unit of negative electricity, the electron". . . . Proton and electron—positive and negative—sulphur and mercury—Sol and Luna—masculine and feminine—Yang and Yin—Osiris and Isis—sun-god and moon-goddess: what a curious appeal this doctrine of the Two Contraries has made to the human intelligence throughout the ages! The wheel turns full circle, and the father-god and mother-goddess of the ancient civilizations reappear in the latest conception of the atom. So, too, the tail-eating snake of ancient Egypt reappeared some two thousand years later in the "Chrysopsis" of Cleopatra, and came once again in these latter days to whirl mockingly before the eyes of August Kekulé, whose fleeting vision of this ancient symbol of eternity gave birth in 1865 to the conception of the benzene ring—"the crowning achievement of the doctrine of the linking of carbon atoms".

Of chemical theory we may exclaim: "Plus ça change, plus c'est la même chose!" It is true that we have elaborated the alchemists' doctrine of the unity of matter and their sulphur-mercury theory of the constitution of metals; and that the modern imagination has bodied forth the proton, the electron, the positron, and the neutron (this last being the latest expression of the alchemical Rebis); but when we try to formulate the ultimate realities of matter we find them as elusive as that *ignis-fatuus* of alchemy, the Philosopher's Stone—the faith of Monday, Wednesday and Friday is the heresy of Tuesday, Thursday and Saturday. Is the path of scientific inquiry into the

fundamental nature of things fated to lead beyond the limits of human understanding into a four-dimensional world as unintelligible as the wild mysticisms of alchemy? Or will the Ouroboros Serpent, at the psychological moment, bring further enlightenment, in another vision, to some future seer of the sub-atomic world?

In these days, when an ever-increasing specialization threatens to produce a generation of

chemists running in blinkers, it is hard to find an all-round master of the science who is able to see it steadily and see it whole, and to depict it in its full coherence and beauty. Prof. Findlay is such a master, and all who have the interests of chemistry at heart will be grateful to him for producing this admirable account of the growth and present state of the science.

JOHN READ.

Atomic Spectra and Atomic Structure

(1) Atomic Spectra and the Vector Model

By A. C. Candler. Vol. 1: Series Spectra. Pp. viii + 237 + 4 plates. 15s. net. Vol. 2: Complex Spectra. Pp. vi + 279 + 4 plates. 15s. net. (Cambridge: At the University Press, 1937.)

(2) Atomic Spectra and Atomic Structure

By Prof. Gerhard Herzberg. Translated with the co-operation of the Author by Prof. J. W. T. Spinks. (Prentice-Hall Physics Series.) Pp. xv + 257. (New York: Prentice-Hall, Inc.; London, Glasgow and Bombay: Blackie and Son, Ltd., 1937.) 4.25 dollars; 18s. 6d. net.

(1) MR. CANDLER'S two volumes upon atomic spectra will appeal to the spectroscopist rather than to the general reader. As the title implies, the whole work is developed on the vector model of the atom. There is a good deal to be said for a book of this nature, for the fact remains that most practical spectroscopists use the vector model in analysis and only turn to the wave mechanics solutions when vectors break down. There is, however, frequent reference to the findings of quantum mechanics, and an introductory chapter on this might well have been included. Throughout the book the historical method of approach is used, the result being an essentially empirical introduction to each branch of the subject. Both volumes contain much detailed material bearing on fundamental principles.

The first volume deals with series spectra and has a general introduction which is clearly written. A good deal of space is justifiably devoted to a very full description of the Zeeman effect, and this is followed by an excellent chapter upon atomic magnetic properties. The description of the Stark effect is rather more detailed than the accounts usually met with in a book of this nature, but this is all to the good. The chapter on the Periodic Table of the elements includes a good deal on valency and is of interest to the chemist as well as to the physicist. Extensive tables of g factors, intensities and Rydberg term values are

included, with the view, apparently, of assisting the experimenter.

In the second volume, dealing with complex spectra, there is detailed consideration of individual spectra, a very wide range being covered in order to illustrate the spectral types found in the different columns of the Periodic Table. It is obvious that the author has consulted a large number of treatises and has thoroughly digested a great number of research publications, the resulting summary being certainly effective. An unusual chapter of interest is that dealing with the line absorption spectra of solids. A good chapter on intensities in line spectra has been included, but the intensities in hyperfine structures seem to have been neglected. Throughout this volume, as in the first, the value of the Zeeman effect is correctly stressed, each point of theoretical interest being supported with a wealth of experimental detail.

The chapter on hyperfine structure is not so satisfactory as the rest of the book, containing some omissions and errors. It is stated, for example, that no absolute measurements of hyperfine structure intensities have been made, but at least four papers on this subject have appeared since 1931. The nuclear spin given for iodine on p. 204 is the earlier incorrect value, and it is questionable whether the author is justified in assuming that, in even isotopes, absence of hyperfine structure means zero spin. The hyperfine structure Zeeman effect is treated with the same clearness that characterizes the description of the ordinary Zeeman effect, and a useful summary is given of the applications of observed nuclear spin properties to the theory of nuclear structure. The interesting method of deriving information about the structure of spectral terms from the study of the depolarization of resonance radiation might have been included.

The last two chapters in the book deal with forbidden transitions and with fluorescent crystals, the latter being particularly well done. Incidentally,

it is time spectroscopists adopted uniformity in the description of forbidden transitions. Mr. Candler uses the term "quadrupole radiation" whilst Prof. Herzberg, in writing of the same thing, calls it "quadrupole radiation". Both notations are unfortunately in regular use.

There are many beautiful plates and diagrams in the work, which is essentially descriptive, easy to read and free from difficult mathematics. It ends with valuable lists of papers on the spectra of each atom and on the hyperfine structures in the spectra. The latter compilation is, I believe, the first of its kind to appear in print and will be found useful by the research worker. Considering the amount of material in the book, the errors are few and far between. It is an excellent treatise for spectroscopists and for investigators wishing to undertake spectroscopic work on line spectra.

(2) The book by Prof. Herzberg is a translation of his recent work "Atom Spektren und Atomstruktur" (Dresden, 1936). It is an introduction to atomic spectra and atomic theory, and is admirably suited to those physicists and chemists who wish to become acquainted with the elements of the subject. Beginning with the elementary Bohr theory of the hydrogen spectrum, the author goes on to show how the vector model breaks down as soon as the helium spectrum is considered, and proceeds to explain why the wave mechanics treatment is necessary. The introduction to the wave mechanics picture of the atom is particularly lucid and is deprived of the terrors usually associated with it in the mind of the student. Throughout the book the vector model and the quantum mechanical view are skilfully blended together into a unified description of atomic processes. A useful point is that certain more difficult paragraphs giving rather detailed wave mechanical explanations are printed in small type and can,

if so desired, be avoided by the reader without destroying the continuity.

The field covered by the book is very wide. The treatment of the Zeeman effect is particularly clear, a careful balance being maintained between vector theory and wave mechanics. The Stark effect is much more briefly dealt with. It is unfortunate that the important table on p. 127 exhibiting the application of the Pauli principle has such tiny lettering that the suffixes can only be read with difficulty. Perhaps too much of chapter iv is included under small type, since, surely, all should read the important details given on series limits, perturbations and jj coupling. The same chapter includes a brief but very clear and precise exposition of auto-ionization. Considering the scope of the book, the chapter on hyperfine structure is reasonably complete, but again one meets the unjustifiable association of zero nuclear spin with absence of fine structure in even isotopes. This remains yet to be proved, and should be qualified in a book of an introductory nature.

The last chapter will be greatly appreciated, particularly by chemists. It deals first with atomic magnetism and then devotes a good deal of space to the applications of the known facts about atomic ionization potentials, a complete table of which is given. Amongst the subjects covered in this chapter are electron affinity, collisions of the second kind and the quantum theory of valency.

The book is illustrated by excellent diagrams and by a number of very good plates. It is only on the rarest of occasions that evidences of the German original peep through the excellent translation. This book deserves to become popular and to become widely read. Students in particular will find it a very valuable introduction which will bring them right up to the most recent developments.

S. TOLANSKY.

Chemical Engineering: Position and Prospects

The Transactions of the Chemical Engineering Congress of the World Power Conference, London, June 22—June 27, 1936

Vol. 1. Pp. lxxxv+525. Vol. 2. Pp. vi+664. Vol. 3. Pp. vi+797. Vol. 4. Pp. vi+751. Vol. 5: Index. Pp. v+164. (London: Percy Lund, Humphries and Co., Ltd., 1937.) 5 vols., £12.

EIGHTY-THREE pages at the beginning of vol. 1 contain a very complete record of what took place at the first Chemical Engineering Conference of the World Power Congress, and include an account of the various functions as well as a list of the members of the Conference.

The remainder of this volume is devoted to an important subject to the chemical engineer, namely, the materials available for the construction of chemical plant. Since iron and steel still constitute the principal materials used by the engineer, the first section is devoted to this subject and the recent developments in the manufacture of ferrous alloys and their properties. In the second section of this volume are papers on the non-ferrous metals, refractory materials, stone-ware, rubber, plastics, and the use of fibrous materials, all of which are used in the formation of apparatus employed in various branches of the chemical industry.

Twenty papers, all dealing with the important subject of separation in its various aspects, such as separation without change of phase or physical state, separation with change of phase or physical state, and separation involving physical reaction, form the first part of the second volume, whilst the later portion of the volume comprises three papers relating to fine grading and the estimation of finely divided solids, and eight papers on electrolysis and the production, application and development of electricity in the chemical industry.

The contents of the third volume are divided into four sections, the first of which consists of eleven papers on destructive distillation, more especially in its relation to the gas industry, as well as the blending of coals for this purpose and the correlation between the analysis of coal and its carbonization in semi-scale and industrial plants. Waste materials and the disposal of effluents form an important problem both to the industrialist and to the individual members of any community and are discussed in four papers in the first part of the next section, whilst three other papers in the second part are concerned with the production, treatment and properties of lubricating oils.

High pressures and vacua are now being more and more extensively used in industry, so it is appropriate that seven papers on these subjects should be included in the third section of this volume, in which papers on the technology of high vacua, construction of welded pressure vessels, synthesis of organic compounds, and liquid and gaseous phase reactions under high pressure are presented.

Since the addition or removal of heat is an important feature in many chemical operations, it is not surprising that the last section of this volume is given over to this subject. In the nine papers presented, such aspects as thermal compression, condensation of vapours and mixtures of vapours and gases, and other important factors connected with the application of heat in industrial problems as well as the mechanism by which the transference of heat is actually effected, have been considered.

Vol. 4 also comprises four sections, the first of which is devoted to the education and training of a chemical engineer and contains seven papers. Considerable difference in opinion has been expressed from time to time on the question of the education and duties of the chemical engineer, so that this section should prove one of the most valuable in the volume and one which should be helpful in future conferences, as it indicates the views of the leaders in this subject in those countries where classes exist for the training of industrialists of this type.

To anyone engaged in the administration of an industrial concern such subjects as efficiency, planning and control of chemical works, prevention of accidents therein and the methods of analysing the cost of a process, which form the themes of seven papers in the second section of this volume, are of interest and importance.

Under the heading of trend of development are thirteen papers upon a variety of subjects which can be broadly classified into three groups, namely, treatment of water for both steam raising and industrial purposes; the heavy chemical industry comprising sulphuric acid manufacture, phosphatic fertilizers and the production of calcium carbide; and thirdly, papers relating to biological processes such as fermentation, fumigation and refrigeration, all of which are included in the general term of chemical industry.

In the last section of this volume and the last session of the Congress are a group of eleven papers classified under the heading of general aspects, which can be conveniently subdivided into two subsections, namely, those papers relating to fundamental research and those to applied research. Applied research comprises the development of research laboratories by large industrial organizations, the applications of the results obtained either from fundamental or applied research to the design of chemical plant, and the investigation and study of the raw materials of a country and their utility to chemical industry. At the end of each section is a report showing the main features of each paper in that section which might form the basis for discussion, and this is followed by the discussion which took place on the papers contained in that section.

Several factors have apparently influenced the grouping of the papers, of which one of the most important was the time available for presentation and discussion, which in many instances was too short for the importance of the subject under review. The different interpretations placed upon the term chemical engineer having been to some extent clarified during this Congress, should result in the papers submitted to subsequent conferences of this kind being even more germane to the subject.

Any review of this publication would be incomplete if no mention were made of a fifth volume of one hundred and sixty-four pages which has been very carefully prepared and edited, comprising both subject and name indexes.

These books should prove a very useful addition to any library dealing with their subject, since they give world-wide views on the various aspects of a large and complex problem.

One cannot conclude without expressing appreciation of the manner in which these transactions have been printed and edited.

Corrosion of Metals

Metallic Corrosion, Passivity and Protection

By Dr. Ulick R. Evans. Pp. xxiii + 720. (London: Edward Arnold and Co., 1937.) 45s. net.

THE importance of corrosion and protection of metals and alloys against corrosion especially to engineers, chemists and metallurgists needs no emphasis to-day. Wherever and whenever the commoner metals are used, corrosion may make its appearance. A significant feature of the study of corrosion is the enormous amount of investigation work that has been done during the past ten years. Dr. U. R. Evans has wisely taken the course of writing an up-to-date account of the subject as it stands at present in preference to revising his earlier book on "Corrosion of Metals", the last edition of which appeared in 1926.

The research work of Dr. Evans on corrosion is very well known not only to engineers and manufacturing chemists, to whom the new work is addressed, but also to the wider realms of science and technology of modern civilization. During the last ten busy years of corrosion-science, Dr. Evans has been the leader of a strong team of research workers at Cambridge, from which notable contributions to knowledge have emerged in a steady stream. For these reasons alone a new survey of the study of corrosion by Dr. Evans will be welcomed. Although fitting mention is made of Cambridge work, the author has not given undue prominence to it, but on the other hand has given a well-balanced account of his subject. The task of summarizing existing knowledge of corrosion is indeed an immense one, especially as the literature is so widely spread and so rapidly increasing in volume. No other author has attempted a work of these pretensions, and the new volume appears likely to occupy a unique position for many years to come.

The arrangement of the subject-matter is on a scientific basis. The author's aim is to unfold the facts leading to an understanding of the causes of the various types of corrosion, without which understanding the attempt to apply remedies may, as the author points out, be dangerous. There are fifteen chapters each dealing with a special aspect of corrosion or passivity. The treatment is somewhat unusual in that each chapter is divided into three sections, the first or *A* section of each being concerned with the scientific basis, the second or *B* section with practical problems, and the third or *C* section with quantitative treatment. This arrangement of the subject-matter should prove of value to readers who for various reasons are

more concerned with the practical aspects than the theoretical or with quantitative aspects rather than qualitative.

Separation of the aspects of corrosion studies in this way has not prevented the author from directing attention to all points of view, achieved by presentation of very interesting subject-matter in a well-sustained manner. The reader must inevitably find himself penetrating the *B* sections even though he may have intended at first to peruse the *A* sections. This is truly a good feature and bears on the larger treatment of corrosion matter, since the subject is one which does not lend itself to empiricism. To escape the ravages of corrosion it is necessary to know not merely what is the cause but also in what manner the prevailing conditions are of influence in one way or another. In matters of corrosion, scientific treatment has ploughed stubborn ground, and those concerned with any aspect of corrosion will be the better fitted to cope with their problems the closer their acquaintance with the basic principles.

The importance of surface films on metals revealed by researches of the modern age of corrosion-study demands for them a prominent position in any treatise on corrosion, and the author appropriately devotes the opening chapters to this side of the subject. Here a useful résumé of pickling methods and results of research on pickling is well placed in view of the recent advances in pickling treatment of iron and steel, for example, to leave a protective film of phosphate on the surface with benefit to the protective effect of paints. The next chapter deals with oxidation at raised temperatures, a subject of high importance in many branches of industry.

In the next five chapters, atmospheric corrosion, tarnishing, corrosion in stagnant liquids, corrosion in moving liquids, hydrogen evolution and influence of constituents of the liquid are reviewed and discussed fully. In view of the multiplicity of factors involved and the interdependence of effects, it is not a matter of surprise that in these fields of corrosion-study different conceptions arise. In this connexion the author fittingly presents a considered statement by Bengough and Wormwell summarizing their views on corrosion of metals in salt solutions, a field in which they have made extensive researches.

The next two chapters deal with the influence of intrinsic features of metals and alloys upon corrosion. From this aspect of corrosion-study notable lines of advance have been followed to fruition, and perusal of this portion of the book

leaves the reader with an impression of the great scope for further advances as further basic knowledge is gained.

A chapter is devoted to the influence of stress and strain, and here a survey of corrosion fatigue research is given. Corrosion fatigue is one of the youngest branches of corrosion-study, and the results have been, to say the least, alarming to engineers. As in other fields, however, systematic experiments and scientific treatment are yielding information of practical value.

The rest of the book is devoted to the influence of contacts and crevices, protection by metallic coatings, protection by paints and enamels and corrosion testing, with an appendix on optical measurement of film thickness.

The book is a rich mine of information on corrosion problems and will prove of value to all chemists, engineers and metallurgists. It seems doubtful whether the binding will endure the hard use that many of the copies will surely find.

H. S.

Developments in Air Navigation

Air Navigation

British Empire edition. By Lieut.-Comdr. P. V. H. Weems, U.S.N. Edited by Arthur J. Hughes and P. F. Everitt. Pp. xiii + 490. (London: McGraw-Hill Publishing Co., Ltd.; New York: McGraw-Hill Book Co., Inc., 1937.) 30s.

THIS book presents clearly and systematically the theory and application of the present methods of air navigation, which form an integral part of the duties of the long-distance or 'deep sea' aviator. In the course of preparing this edition, the author has been in touch with officials of the Admiralty, Air Ministry, Imperial Airways, Air Service Training and others.

The rapidity with which the air pilot must determine his position—if it is to be of any value—has in recent years led to an overhaul of the abridged methods of the mariner, and, indeed, to the development of a school of air navigation. The fundamentals of dead reckoning and celestial navigation are common to all branches of the work, whether on land, on sea, or in the air; it is largely to the introduction of improved and abridged tables combined with the use of specialized instruments that the present advance in speed and simplicity is due. In short, the more quickly the observer must obtain his position, the more dependent has he become on the technical and instrumental side of the work. In this connexion Commander Weems has had the co-operation of Mr. A. J. Hughes, through whose public spirit the preparation of this edition is largely due.

The air pilot cannot stop on account of sudden fog or bad weather, and is thus forced to have at all times a fairly accurate knowledge of his position. For this purpose he employs pilotage, dead reckoning, radio and celestial navigation. Over stretches of uniform country, as for the mariner in open sea, pilotage may not assist, and dead

reckoning is handicapped by unknown variations in the direction and force of the wind, a factor of far greater importance for the aviator than for the mariner. Position lines from radio bearings are limited by the proximity of transmitting stations, and celestial navigation is, of course, dependent on visibility, though here the aviator has some advantage over the mariner in that he can usually rise above the clouds, while his bubble sextant is independent of the sea horizon. It is due to the development of the bubble system of artificial horizon that the navigators of the air and sea are now able to observe with equal facility throughout the twenty-four hours to within 5' or, under favourable conditions, considerably less. Improvements in the bubble sextant are in progress, and a type that will automatically register the mean of a series of six settings is under construction. To the list of observation reduction tables is to be added the forthcoming "Hughes Tables for Sea and Air Navigation", which appear to be a decided improvement on anything of their kind yet published. For air navigation time may be further saved by the use of precomputed altitudes, of which a full description is given.

Comprehensive descriptions, liberally illustrated, of all relevant instruments in use both in Great Britain and in America are found in appropriate parts of the text. The early chapters deal with charts, maps, projections, and their application to set requirements. The section on abridged methods of celestial navigation will be of particular interest to all navigators; it is perhaps as clear an introduction to this branch of the work as has hitherto been published.

The necessary, but often curtailed, explanation of the *Nautical Almanac* is further assisted by a comparison with the new *American Nautical Almanac*. In the latter is tabulated the Greenwich hour angle of the principal heavenly bodies, and

by this means the necessity for a knowledge of right ascension, sidereal time, the first point of Aries, or the equation of time is automatically eliminated.

The section on meteorology has been contributed by Dr. Sverre Pettersen, an international authority on the air mass theory.

It is a matter of opinion whether all the examples of the methods advocated are ideally chosen, and the present writer is not impressed with the nature of the star chart in the folder. Nevertheless, the book can be recommended with confidence to the aviator, navigator, or exploratory surveyor alike.

G. C. F.

Theory and Practice of the Calculus

The Elements of Mathematical Analysis

By J. H. Michell and M. H. Belz. Vol. 1. Pp. xxiv + 516, Vol. 2. Pp. xii + 517-1087. (London: Macmillan and Co., Ltd., 1937.) 42s. net each vol.

THE authors have set themselves the task of writing a treatise on the differential and integral calculus which should be at once practical and rigorous, while assuming only the minimum of previous mathematical knowledge. The emphasis, however, is on the practical side, the book being, to quote the dust-cover, "adapted to the particular needs of students of science and engineering".

A fairly full account of the elementary theory of functions of one real variable is given, though not enough to cover the requirements of an honours degree in mathematics. Where an appeal must be made to an unproved theorem—for example, concerning differentiation of $f(x, y(x))$ —the reader's attention is directed to the fact; and, where possible, the theorem is made to appear plausible by being proved or verified in some special case. A good feature is that in several places a strict mathematical treatment is followed by a paragraph entitled "Working Notions", in which the student is shown how loose intuitive ideas suggest or recall the result.

The presentation of the theory is, in the main, well suited to the class of students for which the treatise is intended. For example, in the main body of the work the idea of the non-terminating decimal is taken as fundamental (the Cantor theory of numbers being explained in a final chapter). This introduces very naturally the method of continued decimal subdivision to prove the fundamental theorems. One might wish, however, that this important method were rather more fully explained. Continuous functions are introduced at an early stage, and the limit of a function is dealt with by means of the easily grasped idea of potential continuity. On the other hand, the "general principle of convergence" is derived from a general discussion of limit-processes, which appears to the reviewer to be too abstract

and difficult. Taylor's theorem is very well treated, losing that air of mystery which too often surrounds it. Integration is defined as the inverse of differentiation, the Riemann integral being introduced, but discussed only for a continuous integrand. Curvature, length, area and volume are dealt with rigorously but comprehensibly.

Mathematical rigour in language is usually maintained, but in one place we have "finite" for "bounded", while there seems to be a slight slip in the proof of the limit-sum integral formula. There are a few departures from standard terminology, some of which, such as the distinction between "upper barrier" and "upper bound", are good; while others, for example, "upper continuity" (for continuity on the right), seem likely to lead to confusion.

The practical side of the book is good. There are many worked examples and a large collection of problems. Maxima and minima, interpolation, Newton's method for solving an equation, and other applications of the derivative and of Taylor's theorem are thoroughly dealt with. The trigonometric, exponential and hyperbolic functions are discussed at length and used as examples of methods previously explained, while the cycloidal and epicyclic functions also are introduced. There is a long section on the standard forms of integrand (with recurrence formulæ), and approximate methods of integration are not neglected. Special emphasis is laid on the calculation of the uncertainty in approximations. There is a section on curves, and one on polynomial approximation by various methods. Finally, we have an introduction to differential equations, the second order equation with constant coefficients being completely discussed. It is perhaps a pity, from the practical point of view, that the authors here keep strictly to the domain of the real variable.

To sum up, the book may be recommended to all those who wish to know something of the mathematical discipline of function-theory, but whose main concern with mathematics is as a tool.

A. J. WARD.

Short Notices

Anthropology and Ethnology

A Tribal Survey of Mongalla Province

By Members of the Province Staff and Church Missionary Society. Edited by L. F. Nalder. (Published for the International Institute of African Languages and Cultures.) Pp. viii+232. (London: Oxford University Press, 1937.) 15s. net.

THIS collective work by Government and mission officials in the most southerly part of the Anglo-Egyptian Sudan may be regarded as a supplement to the studies of O. G. and B. Z. Seligman, Driberg and Evans-Pritchard. It contains useful information, particularly about several tribes for whom hitherto there has been scarcely any published material available, and bears witness to the painstaking interest of European residents of the area in the institutions of the native peoples among whom they work. A feature of note is that nearly all the data have been collected in the vernacular.

But in view of this it is to be regretted that, except for Mr. Mynors on the Moru and Mr. Arber on the Latuka, scarcely any writer has supported his generalisations by quotation of native statements or distinguished what he actually observed from what he was told. In the absence of such empirical records, statements such as "the people's ideas [on religion] are generally very vague and unco-ordinated" or "the basis of Bari society is the clan" or "the Lango women are very liable to hysteria" are of small value. Moreover, even in matters which are comparatively easy to observe, there are many gaps in the analysis which could have been filled. In the chapter on tribal structure there is no section on family life; and the meagre summary of economic life (less than four pages) deals almost solely with technical processes, without reference to methods of productive organization and exchange.

The book has much interesting comparative material, and suggests lines for future inquiry; but it illustrates also how necessary it is nowadays that enthusiasm and hard work should be backed up by systematic anthropological training.

R. F.

Anthropology:

an Introduction to Primitive Culture. By Prof. Alexander Goldenweiser. Pp. xxi+550+80 plates. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1937.) 18s. net.

PROF. GOLDENWEISER'S "Anthropology" was undertaken originally as a revision of his "Early Civilization"; but in the process of expansion it has grown into a new book. It now falls into three parts. The first, "Animals, Man and Culture", deals with man's place in Nature, and his relationship, physical and psychic, to the animal world, as well as his reactions in the development of culture; the second, "Primitive Life and Thought", discusses in twenty-two chapters culture traits, both material and social in

the broader sense, in the light of specific examples as exhibited in varied cultural environments; and in the third, "The Ways of Culture", certain general problems of theoretical import are considered in four chapters on culture and environment, the spread of culture, and evolution and culture. This last section will be particularly valuable to the student. It is a well-balanced and objective examination of topics into which controversial methods are apt to introduce some, however little, distortion. A chapter on "The White Man's Burden" deals with the deplorable effects on backward peoples of contact with white civilization, and describes the efforts which are being made in the United States under the legislation of 1934 to reintegrate the tribal culture of the Indian. Prof. Goldenweiser, while generally approving the object, confesses that he is not an optimist as to the result, although the Indians have shown themselves eagerly ready to take advantage of the offers made by the Government.

Biology

Atlas of the Scale Insects of North America

By G. F. Ferris. Pp. 280+104 plates. (Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1937.) 40s. net.

THIS is the first section of a large work undertaken by Prof. G. F. Ferris of Stanford University, who has for many years made a special study of scale insects. The author hopes eventually to deal with every species of scale insect that is definitely established in North America and to make possible their identification. The "Atlas" is primarily a collection of well-reproduced plates of admirably clear drawings illustrating each species, with brief notes on synonymy, hosts and distribution, habit, and the chief recognition characters; and the matter concerning each species can, if desired, be obtained separately in loose-leaf form.

In an interesting introduction describing the plan and basis of the work, Prof. Ferris also discusses the system of classification adopted. He considers that the old family Coccidae "must be stepped up at least to a super-family", Coccoidea, within which he recognizes eleven families occurring in North America. Among these, the Diaspididae is divided into the sub-families Diaspidinae and Phoenicococcinae, and the volume under notice deals with the tribe Diaspini of the former sub-family. This covers some 34 genera, including species of *Aulacaspis*, *Ohionaspis*, *Diaspis*, *Epidiaspis*, *Lepidosaphes* and *Parlatoria*. The debatable problem of the genera to be accepted is shortly discussed, the author admitting that it "cannot be settled to the satisfaction of everyone, or perhaps even of anyone, the author included". About a hundred species in all are illustrated and, as a rough estimate, it is thought that the complete "Atlas" will include perhaps 750 species.

The difficulties of identification of scale insects are considerable, but they are a highly interesting group from the taxonomic point of view and have the added attraction that many species are of great economic importance and wide distribution as pests. In spite of this their study has been much neglected, and all who are interested will be grateful to Prof. Ferris for undertaking the valuable publication, which should prove a stimulus to further work.

Some Beautiful Indian Trees

By the late Rev. E. Blatter and Walter S. Millard. Pp. x+110+68 plates. (London: John Bale, Sons and Curlew, Ltd., 1937.) 21s. net.

THIS book represents the elaboration of materials already published in the *Journal of the Bombay Natural History Society*. 31 beautiful coloured plates, 35 full-plate photographs and 42 line drawings in the text of 108 pages are ample and excellent illustrations for the guidance of those who desire to acquaint themselves with some of the striking trees that are frequently met with in the plains of India. Detailed descriptions of the more common species have been given, together with notes on their distribution, economic uses and gardening. A long list of popular names has also been added. Suitable English names of some of the species have been coined. The generic name is followed by an appropriate explanatory note. The book is nicely bound and well printed.

But such rich materials lack in proper arrangement and uniformity in the treatment of families, genera and species dealt with in this volume. Such want of sequence in the subject-matter is a bit confusing to the reader. Notes on distribution might have been made more useful by incorporating further details of localities by consulting herbarium specimens of different parts of India and Burma. The lists of popular names in some cases are too long. The names of some of the species require slight modification in the light of the international rules of botanical nomenclature.

The book is entitled "Some Beautiful Indian Trees"; but some of the species dealt with are not indigenous to India.

Although there is room for several improvements in the book, yet it is indeed a laudable attempt on the part of the authors towards better recognition of some of the attractive Indian trees. The volume is a valuable addition to the Indian botanical publications. It will undoubtedly prove useful to the lovers of plants, both Indians as well as foreigners visiting India.

Mytilus

By Kathleen M. White. (Department of Oceanography, University of Liverpool: L.M.B.C. Memoirs on Typical British Marine Plants and Animals, 31.) Pp. vii+117+10 plates. (Liverpool: University Press of Liverpool; London: Hodder and Stoughton, Ltd., 1937.) 9s. net.

SIR WILLIAM HERDMAN did a good day's work forty years ago when he planned out for the Liverpool Marine Biological Committee the series of papers

known ever since as the "L.M.B.C. Memoirs". They have put on record, in more or less detail, the structure and natural history of one common animal after another—no small service; for, as Huxley once said, if the commonest of our British animals became suddenly extinct, we should find we knew next to nothing about many of them. The writing of these memoirs has trained the prentice hand of many a naturalist, among them Ashworth and James Johnstone, Cole, Dakin, Eales, Fleure, Hickson, Imms and Punnett. A new part still comes out every now and then, and No. 31 has just appeared; it is by Miss Kathleen White of Reading, on the common mussel.

Abundance, cheapness and convenient size all fit *Mytilus edulis* for students' use, but it is not very easy to dissect—until you know how. Miss White gives a clear and full account of its anatomy, with the part on the circulatory system particularly good; her figures are excellent, and her brief instructions for dissection are very much to the point. There have been several other monographs on the mussel since de Heide wrote a book on its anatomy two hundred and fifty years ago. Seventy years ago Sébaste began an elaborate study, but never finished it; Field wrote a better and more complete one in a bulletin of the U.S. Fisheries Bureau; now Miss White has given us the best and handiest of them all.

Biology for Students of Pharmacy

By E. J. Moore. Pp. vii+415+8 plates. (London: Edward Arnold and Co., 1937.) 15s. net.

ELEMENTARY biology is one of the basic subjects for several types of students reading for professional degrees or diplomas such as in agriculture, medicine, dentistry, pharmacy and so forth. A general elementary course in biology should satisfy all needs, yet since most professional examining bodies set their own syllabuses, he would be an ambitious author who attempted to satisfy all requirements in one text-book.

A course which is really a combined one of botany and zoology is not the kind of biology which meets with approval to-day; but the author of this book disarms this justifiable criticism of his work by stating explicitly that "the arrangement of the chapters has been decided partly by the fact that the published syllabus [of the Preliminary Scientific Examination of the Pharmaceutical Society of Great Britain] is divided into plant and animal sections". So he wisely follows the syllabus.

This enforced failing aside, the book can be described as excellent. It is quite clear that the author takes his subject as a serious teacher and has not merely compiled his book from other publications or teaching schedules. The text is quite up to date and very lucid, and the two hundred diagrams and eight plates are so clearly produced and labelled that every student of pharmacy can be sure of getting as much out of the book as he requires.

Teachers and students of biology in the pharmaceutical departments of colleges and universities would do well to consider adopting this book as their standard.

Chemistry

Chemical Principles with particular Application to Qualitative Analysis

By Prof. John H. Yoe. Pp. ix+311. (New York: John Wiley and Sons, Ltd.; London: Chapman and Hall, Ltd., 1937.) 13s. 6d. net.

THE keynote of this book is the correlation of reactions and phenomena encountered in qualitative analysis with the student's training in the theoretical principles of inorganic and physical chemistry. All teachers recognize that qualitative analysis should form a part of the student's training, and too frequently it remains almost a separate compartment of the student's knowledge with little or no correlation with the rest of his chemical knowledge.

Prof. Yoe's book is comprehensive. There appears to be no type of reaction or physico-chemical phenomenon likely to be met with in a well-directed course of qualitative analysis but what is discussed. For example, the nature of solution, oxidation-reduction reactions, co-ordination and stereoisomeric co-ordination compounds, neutralization and hydrolysis, theory of indicators, determination of hydrogen ion concentration, the preparation and properties of colloids, adsorption phenomena, crystal structure, atomic structure and even the quantum theory are some of the topics dealt with. To most chapters there are illustrative set problems, answers being supplied to the numerical ones.

Bearing in mind the size of the book, the range of its contents is surprisingly large. In some cases the result is a lack of clarity undoubtedly due to too great compression. An example of this is the chapter on the electrical theory of matter, radioactivity and atomic structure, which occupies rather less than seven pages, in which the neutron is not specifically mentioned.

As an introduction to specialized text-books and monographs, for which all students do not have time or inclination to study, such a book as this has a useful place in the student's library. C. S. G.

Quantitative Pharmaceutical Chemistry:

containing Theory and Practice of Quantitative Analysis applied to Pharmacy. By Prof. Glenn L. Jenkins and Prof. Andrew G. DuMez. (McGraw-Hill Publications in Pharmacy.) Second edition. Pp. xxv+466. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 21s.

THE gratifying reception accorded to this excellent text-book on its first appearance has led the authors and publishers to issue a new edition, which has been largely revised in order to bring the subject-matter into conformity with the many changes made in the official methods of analysing pharmaceutical materials in the latest issues of the United States Pharmacopoeia and the National Formulary. The theoretical matter has also been brought up to date, while the number of assay exercises has been increased. In addition, the contents have been rearranged, being now divided into three parts instead of four as in the original edition. This compression has been achieved by

deleting the section on ultimate analysis and by incorporating the chapters on pH determinations, electro-analysis, etc., which originally represented non-official procedures, with the other physico-chemical determinations such as refractive index, specific rotation, etc. These are now all contained in Part 2, while, as before, Part 1 deals with gravimetric, volumetric and gasometric methods. The third section is devoted to special procedures such as the assay of alkaloids and volatile oils and the determination of the constants of fats, waxes, resins and balsams.

The volume is well written and produced, and although all the methods advocated are not official in Great Britain, nevertheless they will be found useful to those who are interested in the application of quantitative analysis to pharmaceutical materials.

G. R. D.

The Drama of Chemistry:

How Man deals with Atoms. By Prof. Sidney J. French. (The University Series: Highlights of Modern Knowledge.) Pp. vii+170. (New York: The University Society; London: Chapman and Hall, Ltd., 1937.) 4s. 6d. net.

It requires confidence and wide knowledge to give a stimulating account in a small space of the work of the chemist through the ages, to discuss something of the future of the science and to suggest how a more detailed knowledge of it may be obtained. Dr. French has tackled his difficult task boldly.

The section dealing with organic and biological chemistry is not so satisfactory as those portions dealing with phenomena of solution and with atomic structure. Certain drawbacks are inevitable in a work of this kind. Formulae of some organic compounds need revision and expansion, and the account of Pasteur's resolution of racemic acid is inaccurate. The author surely does not believe that sucrose has been synthesized, that amino acids cannot be condensed together and that Willstatter had nothing to do with the elucidation of the structure of chlorophyll!

It may also seem strange that an account of the development of our knowledge of atomic structure can be given without mentioning the names of Sir J. J. Thomson and Lord Rutherford. While later workers are referred to, Prof. F. Soddy's pioneering work on the isotopic forms of the elements is overlooked. On the other hand, "Henry Armstrong", according to Dr. French, was famous for having dared to oppose Arrhenius's dissociation theory and is described with Louis Kahlenberg as being "chief among the hardy rebels".

In spite of these criticisms, Dr. French has given us a most readable and brief account of what he aptly describes as "The Drama of Chemistry".

C. S. G.

Practical Organic Chemistry

By A. J. Mee. (Dent's Modern Science Series.) Pp. x+284. (London: J. M. Dent and Sons, Ltd., 1937.) 5s.

THE author has managed to compress nearly three hundred experiments into this little volume, which is intended to be used in conjunction with a text-book

dealing with the underlying theories. The aim has been to provide a course of instruction in practical organic chemistry up to pass degree standard, consisting of preparations of compounds, arranged to illustrate the main groupings of the subjects and of typical reactions of many of the prepared compounds. Two short chapters at the end deal respectively with the application of dyestuffs and the identification of unknown compounds. Quantitative analysis has been omitted. A very useful feature of the book is the inclusion at the beginning of some of the chapters of tables showing the chemical relationships of the products described.

It is rather surprising to find the old-fashioned method of drying glassware with alcohol and ether mentioned. In Fig. 16 the positions of the manometer and the safety-flask might have been interchanged and the use of rubber stoppers avoided entirely. In testing for the elements, Lassaigne's reaction with sodium often fails; Middleton's reagents (sodium carbonate and zinc dust for nitrogen and pure sugar and sodium carbonate for sulphur and the halogens) are both safer and more satisfactory. The book covers a fairly wide field and the instructions are very clear and concise.

Engineering

Aerodynamics

By Dr. N. A. V. Piercy. Pp. xvi+423. (London: English Universities Press, Ltd., 1937.) 30s. net.

DR. PIERCY has, to use a hackneyed phrase, "fulfilled a long felt want" in producing this book. Although there are several excellent English books on aerodynamics, the exceptional rate at which the applied outlook of the subject has developed recently has left a distinct gap in text-book literature, although such information is available in a more scattered form in periodicals, Government publications, etc. Students and professional technicians will certainly find this volume an indispensable companion.

In keeping with the breadth of his title, the author attempts to survey the whole field of his subject, and merely because of lack of space fails to do some parts of it justice. This is a pity, in a book from so able an author and unquestionable an authority as Dr. Piercy, but on the other hand the treatment is logical. Discussions start *ab initio*, and treat the subject properly up to a certain point. This makes a book that appeals to the student rather more than to the professional aerodynamicist. Is it too much to hope that this will be followed by a second volume with a more practical aspect?

Such matters as the rotating wing, interference, movements of the transmission point and the measurement of profile drag, the empirical treatment of the subject of skin friction and the boundary layer, are a few of the questions that aircraft designers need to see treated from their applied point of view. The last chapter, dealing with the analysis of performance, is exactly what is required by the practical reader, and provokes one to hope for more of this sort of treatment in either an extra volume or a second edition.

Engineering Properties of Soil

By C. A. Hogentogler, with the collaboration of Henry Aaron, Richard C. Thoresen, Edward A. Willis, and Adolph M. Wintermyer. Arranged and edited by C. A. Hogentogler. Pp. xiii+434. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 30s.

SOILS are a subject of interest to a large circle of investigators, since they play an essential part in most human activities. Not least are they of importance to the engineer, who has to deal with them as foundations and as materials for his structures. A text-book on these aspects of their utility is therefore not only justifiable but also eminently desirable, and the authors of this joint compilation have produced one on clear and comprehensive lines. Part 1 of the volume deals with the origin and composition of soils; Part 2 with the characteristics of soil; Part 3 with the structural properties of soil; and Part 4 with practical design and construction. The chief author and his collaborators are highway engineers in the service of the United States Bureau of Public Roads: their point of view, therefore, as well as the sources of their data, is naturally mainly American, as is evidenced throughout the volume in nomenclature and classification and in the fairly extensive bibliography at the end. The book is well illustrated with diagrams, and there is a glossary of geological terms as well as a serviceable index.

B. C.

An Introduction to Fluid Mechanics

By Alex. H. Jameson. Pp. x+239. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 7s. 6d. net.

RECENT developments in aeronautics, the turbine and the use of liquid and gaseous fuels have produced a great change in the science of fluid mechanics. As a consequence, an elementary knowledge of the modern advances in the subject is now required by engineering students. This book has therefore been written for the use, primarily, of second year students preparing for the London engineering degree. The author has made a special feature of keeping the course as free as possible from empirical formulae and tables of coefficients. The text is well illustrated by clearly drawn diagrams and fully worked-out examples. Both the calculus and the method of dimensions have been used wherever necessary, and although the book is designed to cover adequately a specific syllabus, it should be very useful to all engineering students.

Storage Reservoirs

By George Bransby Williams. Pp. ix+293+24 plates. (London: Chapman and Hall, Ltd., 1937.) 25s. net.

WITHIN the modest compass of 300 pages, Mr. Bransby Williams has succeeded in compressing a very comprehensive and up-to-date survey of a subject the full development of which would require a number of volumes. The survey is necessarily

brief and compact, covering as it does a wide range of topics: rainfall, off-flows (or run-offs) and storage capacities; flood discharges and spillway capacities; masonry gravity dams; single arch masonry dams; multiple arch and reinforced concrete dams; earth, hydraulic-fill and rock-fill dams; regulation of storage and reservoir features (including power stations); methods of construction and treatment of water for domestic supplies. In addition to these technical matters, the author finds space to conclude with what he terms an Engineer's Odyssey, being an account of a tour around the dams and reservoirs of Great Britain. Having occupied the post of chief engineer in the Public Health Department of the Government of Bengal, Mr. Williams naturally gives prominence to water storage installations in India, but his survey is representative of the most modern practice in other countries. There are a number of diagrams and some photographs.

B. C.

Philosophy and Psychology

Theory and Art of Mysticism

By Prof. Radhakamal Mukerjee. Pp. xvi+308. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 15s. net.

A book on Oriental mysticism—which being traditional is essentially sound—is nowadays of an actual as well as of a general interest. Europe is suffering to-day from crude and brutal mysticisms; obsessed by an apparently overpowering need of spiritual surrender; the desire for a crazy submission to 'leaders' with a false mythological halo and a perverted racial or nationalistic background. The understanding of how this mental attitude has come upon us in our Western world, what it means, and what it portends for the future, is perhaps the most vital problem of modern social science.

This book, written by one of India's foremost scholars, himself fully in sympathy with the mystical point of view, will be a great help towards the understanding of mysticism in general. The chapters which deal with the "training in the art of contemplation" will assist us in grasping the inner attitude of the mystic. Dr. Radhakamal Mukerjee has already established a world-wide reputation as an economist. He is also a distinguished scholar in social science. The width of outlook and the richness of literary and factual evidence save the work from the one-sidedness from which a piece of special pleading might suffer. The introductory chapters on the foundations of religion, on its primitive manifestations, on magic and ritual, reveal the writer's competence in dealing with anthropological problems. The discussion of the relation between religion and economic life is of special interest because here his appreciation of mysticism and his professional knowledge mingle and cross-fertilize each other. The book will therefore be of value to the student in political science, the economist, and also of course to the philosopher concerned with the history of religion.

B. M.

The Philosophy of Relativity

By Prof. A. P. Ushenko. Pp. 208. (London: George Allen and Unwin, Ltd., 1937.) 8s. 6d. net.

So many books have been written on this important subject that one may almost doubt whether anything really new can be said about it. Yet Prof. Ushenko succeeds in being both interesting and new, thanks to his method of treatment of the theory of relativity. To begin with, he wants philosophers to understand what the mathematics of relativity mean; so in Chapters ii and vi he gives a step-by-step deduction of the main equations of relativity. Then he goes on to give a critical account of the meaning of these equations. He bases his discussion on the fact that events are described by dispositional characteristics, and that they must have an essence which is distinct from these characteristics. For him, this essence is a fusion of space with time, thus rejecting physical substance as an alternative category of natural philosophy, and involving an attitude which is antagonistic to the new positivistic tendencies.

T. G.

Physics

Electrolytic Condensers:

their Properties, Design and Practical Uses. By Philip R. Coursey. Pp. viii+172+10 plates. (London: Chapman and Hall, Ltd., 1937.) 10s. 6d. net.

THOUGH the development of the electrolytic condenser goes back quite a long time, it is only in recent years—mainly through the demand of the wireless industry—that they have reached their present important position. Mr. Coursey's book is the first one published in English on this subject. It is, in the first place, intended for the prospective user, that is, for designers of apparatus incorporating such condensers.

This explains the mode of treatment adopted—in combination with the restraint which the author had to impose on himself as technical director of a firm manufacturing these condensers. We find a bare minimum of information on the physico-chemical processes underlying the action of the condenser, a general survey of the various types of construction and of their electric properties, and a fairly detailed description of the methods used for testing and of the points which have to be considered when selecting a condenser for some definite purpose. The electric properties in question are illustrated by numerous curves, many of which are characteristic; all are, however, presented in a way which makes identification with definite types of condensers or experimental conditions impossible. In order to reach as wide a public as possible a rather elementary mode of presentation has been adopted. There are few references to patents or literature, those given dealing nearly all with circuit problems.

The book will be definitely useful to the research worker who wishes to employ this type of condenser in his experimental apparatus.

A. B.

Alternating Current Measurements at Audio and Radio Frequencies

By Dr. David Owen. (Methuen's Monographs on Physical Subjects.) Pp. vii+120. (London: Methuen and Co., Ltd., 1937.) 3s. 6d. net.

THIS new addition to Messrs. Methuen's well-known series of monographs is devoted to the principal methods used for the measurement of frequency and circuit constants for alternating current in the audio and radio frequency range. Its main contents are as follow: introduction to the treatment of A.C. circuits by vector methods and complex notation, measurement of inductance (self and mutual), capacity and frequency at audio frequencies, mainly by the use of bridge methods, including, however, a special chapter on A.C. potentiometers; measurement of the same magnitudes at radio frequencies by resonance methods. The author, who with the 'Owen bridge' has himself made a definite contribution to the subject, has succeeded in presenting the matter with agreeable shortness, outlining well the points which should be observed in the experimental procedure. Numerous examples, worked out in detail, add to the usefulness of the book by illustrating the order of magnitudes and errors encountered.

A. B.

Miscellany**Interpretative History of Flight:**

A Survey of the History and Development of Aeronautics, with Particular Reference to Contemporary Influences and Conditions. (Board of Education: Science Museum.) By M. J. B. Davy. Pp. 208+31 plates. (London: H.M. Stationery Office, 1937.) 5s. net.

THIS is a fourth volume written by Mr. Davy, of the Aeronautics Section of the Science Museum, South Kensington, which, although not directly descriptive of the exhibits there, is based upon the historical aspect of such an exhibition, and might well be read in conjunction with a visit to it.

The book describes the continuous development of the idea of flight and provides a record of the human activities leading to its achievement. The subject has been dealt with from a somewhat new point of view in that the outstanding phases, facts, and events are explained with reference to the contemporary conditions and the general trend of human development, it being felt that there exists a need for the presentation of this subject in a form which embraces more than bare facts and technical details unrelated to the social and economic background.

It is divided into three parts, and is fully illustrated with contemporary prints and photographs. Part 1 deals with the principles of natural flight and the early history of man's attempts. Part 2 treats the period from the beginning of definite historical records up to the end of the Great War in 1919, that period in which flight was first conceived, then achieved, and afterwards developed towards the wartime outlook exclusively. Part 3 covers the post-War applications to the various transport activities,

and speculates upon the social and economic aspects of the question.

This is a thoroughly readable book, written by an author who is in a position to be, and is, a master of his subject.

Prosperity Beckons:

Dawn of the Alcohol Era. By Dr. William J. Hale. Pp. viii+201. (Boston, Mass.: The Stratford Co., 1936.) 2 dollars.

THE interdependence of industry and agriculture is gradually gaining wider recognition, but current conceptions of agriculture are largely dominated by inherited views of its functions. In this spirited forecast of the possibilities of an era in which alcohol will largely displace petrol and other hydrocarbons as fuel for the internal combustion engine, as a result of developments from the discoveries of Bergius on the hydration of cellulose and Hertz on the isolation of α -cellulose from wood pulp, the author discards such conceptions. The production of food, he suggests, is a purely secondary matter. A fifth of those engaged at present in agriculture could supply all our needs in respect of food and clothing. Agriculture's main business in the future should be the provision of raw materials for industry, especially raw alcohol, or as he terms it, "agriorude alcohol", and the crops to be cultivated should be determined primarily by industrial needs.

In a style which at times borrows too much from the devices if not the jargon of the publicity agent, Dr. Hale gives much food for thought, and the possibilities of advance in the direction he indicates deserve serious attention. His argument for a closer relation between the factory and the farm is reinforced not only as a contribution to the unemployment question and by the importance of utilizing the vast quantities of agricultural waste products, but also by the general tendency of economic nationalism to seek substitutes for materials imported from abroad. At a time when determined effort to formulate a genuine agricultural policy for this country related to the conservation of all its natural resources is long overdue, the book should appeal to all scientific workers who are considering the contribution of science in this field.

Noise

By Dr. A. H. Davis. (Changing World Library, No. 6.) Pp. x+148. (London: Watts and Co., 1937.) 2s. 6d. net.

THE author is well known for being in the forefront of noise studies. The present little book is suitable for the scientific worker who has not yet become acquainted with the many aspects of the noise problem, and for the general reader, who ought to be impressed by the manner in which a social problem can be attacked when treated scientifically. The measurement of noise level and the definition of the phon scale are carefully explained, but the feature of this little book is the amount of well-balanced information which is presented in such agreeable terms.

Observations made in hydrogen light ($H\alpha$) with the Hale spectrohelioscope at Greenwich Observatory showed considerable activity within the spot. Besides the occurrence of several minor eruptions, bright eruptions of large extent were observed on September 29 at 10^h 50^m until 11^h 50^m U.T. and on September 30 at 10^h 28^m until 11^h 30^m. The times of maximum intensity of these eruptions agree closely with those of pronounced fadings in short-wave wireless transmission as recorded in Great Britain and elsewhere. A magnetic disturbance was registered at Abinger from October 3^d 11.3^h until October 4^d 9^h, and an aurora was reported from the Southern Coast of England on the night of October 3-4.

Announcements

PROF. JOJI SAKURAI, president of the Imperial Academy and of the National Research Council of Japan, has been elected vice-president of the International Council of Scientific Unions in succession to the late Marchese Marconi.

GHE. MED. RAT DR. HANS VIRCHOW, emeritus professor of anatomy of the University of Berlin, celebrated his eighty-fifth birthday on September 10, and Dr. Karl Jacoby, emeritus professor of pharmacology and physiology of the University of Tübingen, was eighty years of age on September 12.

THE July issue of the *American Journal of Roentgenology and Radium Therapy* is dedicated to Dr. Henry K. Pancoast, in honour of his twenty-fifth year as professor of roentgenology at the University of Pennsylvania. Dr. Pancoast has served as president of the American Roentgen Ray Society, of the American Radium Society and of the first American Congress of Radiology held at Chicago in 1933.

MISS E. A. LANGLEY, at present organizer of school meals for the London County Council, has been appointed to fill a new post on the staff of the Board of Education as inspector of the arrangements made by local education authorities for the provision of meals. She will co-operate with the Board's medical staff in the campaign for improving the nutrition of school children.

A GRACIOUS tribute to the value of the scientific radio research conducted within the Empire has been recently paid by Mr. J. W. O. Hamilton, who has offered sums to found prizes for radio research at the Universities of Cambridge, Melbourne, Sydney and Tasmania. In his letter to the Vice-Chancellor of the University of Cambridge, offering the sum of £500 for this purpose, Mr. Hamilton has expressed a desire that the names of James Clerk Maxwell and Sir Ambrose Fleming, both Cambridge men, should be associated with the prize.

THE Quekett Microscopical Club is holding a conversazione in the rooms of the Royal Society, Burlington House, Piccadilly, W.1, on Tuesday, October 12, at 7.30.

A SPECIAL course of nine lectures will be delivered at the London School of Economics and Political Science by Bertrand Russell on "The Science of Power" on Mondays at 5 commencing October 11. Further information and forms of application may be obtained from the Secretary, London School of Economics, Houghton Street, Aldwych, W.C.2.

A CONFERENCE on Rubber Technology will be held in London on May 23-25, 1938, under the auspices of the Institution of the Rubber Industry. The president will be Mr. S. T. Rowe. The Conference will be divided into two parts: (1) Methods of Improving and Evaluating the Durability of Rubber; and (2) General Subjects. Further information can be obtained from Mr. W. F. V. Cox, Institution of the Rubber Industry, 12 Whitehall, London, S.W.1.

A GENERAL DISCUSSION on Lubrication and Lubricants, under the auspices of the engineering and technical institutions of Great Britain, is being held on October 13-15. It has been found necessary, owing to the large numbers of applications for membership, to arrange for the discussion to be held in the Central Hall, Westminster, London, S.W.1. In conjunction with the discussion an exhibition will be held at the Science Museum, South Kensington, S.W.7. The exhibits will include lubricants, bearings, applications of lubrication, filtration, testing and research, as well as an interesting series of exhibits from the Science Museum collections. The exhibition will remain open until October 31.

A CHAIR of the history of medicine has recently been founded at Buenos Aires with Prof. Juan Ramón Beltrán as its first occupant.

THE annual meeting of the International Society of Medical Hydrology, which is open to non-members, will be held at Frankfurt-on-Main and the neighbouring spas on October 17-22, when the subjects for discussion will be bioclimatology, psychological factors in health resort practice and the natural history of peats and muds. Further information can be obtained from the secretary, 109 Kingsway, London, W.C.2.

THE twenty-fourth French Congress of Hygiene will be held at the Pasteur Institute, Paris, on October 18 and 19 under the presidency of Dr. E. Léon, member of the Academy of Medicine, when the subjects for discussion, among others, will be school hygiene and wholesome milk. Further information can be obtained from Dr. R. Dujarric de la Rivière, Institut Pasteur, 28 rue du Docteur Roux, Paris 15^e.

ERRATUM. Referring to his letter "Transitive Interference in Gene Linkage" in NATURE of August 21, p. 322, Prof. K. de Kőrösy writes stating that the table on p. 323 contains a misprint overlooked by him in the proof; in column c, line g, for 0.279 read 0.249.

Examination of Synthetic Resins by X-Rays

WE have attempted to study the process of resinification by following with the aid of X-ray diffraction the transitional stages of structure taking place in an initially crystalline compound which on heating forms a resin. Well-known substances of this type are the phenolic alcohols, which on heating form the class of resins termed 'saliretins'. A first result of the X-ray method has been to show that *p*-cresol monoalcohol (2-hydroxy-methyl-4-methylphenol) changes over at an intermediate stage to an apparently new compound to which this note directs attention.

The X-ray transmission spectrum of the initial material is shown in Fig. 1. After heating the substance under a pressure of 17 mm. of mercury for 30 minutes at 180°, the spectrum of the cooled product changes to that shown in Fig. 2, where the original rings, except for faint traces, are replaced by others. The new rings resemble the originals in a

cent; H, 6.98 per cent). It appears to be formed as follows, and to function as a true intermediate:

In addition to the detection of the new compound, further X-ray results in this particular case give more

X-RAY DIFFRACTION PHOTOGRAPHS SHOWING THE FORMATION ON HEATING *p*-CRESOL MONOALCOHOL OF INTERMEDIATE COMPOUND AND FINAL RESIN.

general way but have different diameters and, therefore, indicate a new structure. The isolation of a new compound by fractional extraction with light petroleum, from which it crystallizes in flakes melting at 99–100°, supports this conclusion. The nearness of this melting point to that of the initial material (105°) probably explains in part why the new compound has not previously been noted. The compound has tentatively been assigned the formula 3-hydroxy-methyl-2 : 2'-dihydroxy-5 : 5'-dimethyl-diphenylmethane (I) (found: C, 74.8 per cent; H, 7.29 per cent (micro-analysis); $\text{C}_{18}\text{H}_{18}\text{O}_2$ requires, C, 74.4 per

definite information than usual upon the structure of the resin itself. It will be noted that the characteristic feature of Figs. 1 and 2 is a strong inner ring followed by a gap and then a group of outer strong rings. Now the spectrum of the resin taken under the same conditions, and shown in Fig. 3, shows unmistakably the same characteristics. There is a strong central halo corresponding to the inner ring of Fig. 2 and two outer halos corresponding to the outer rings of Fig. 2. The resin is, therefore, not amorphous but a distorted crystal structure with a molecular arrangement essentially similar to that of the crystalline

intermediate. The resin is, therefore, formed structurally by small irregular relative displacements of the molecules from the crystalline formation and not by radical rearrangement of a random nature.

The size of the unit cell of *p*-cresol alcohol and the arrangement of molecules therein will be described in a more detailed communication.

This research has been carried out at the instigation of Sir Gilbert Morgan, director of the Chemical Research Laboratory, to whom thanks are due for permission to publish the results, and the X-ray work has been carried out under Dr. G. W. C. Kaye, superintendent of the Physics Department, National Physical Laboratory.

Chemical Properties of the Rare Gases

It is known that the rare gases argon, krypton and xenon give unstable chemical compounds with van der Waals bonds, namely, the hydrates. They have been obtained by compressing the gas over water at 0° C. In the case of argon, the crystals of the hydrate are formed at a partial pressure of argon of about 100 atm. I have already shown by an independent method¹ that radon, too, forms a hydrate which is much more stable than those of other rare gases. Radon is easily held by crystals of sulphur dioxide hydrates, when they are formed from snow and sulphur dioxide below the eutectic point or recrystallized. The radon hydrate is isomorphous with the hydrate $\text{SO}_2 \cdot 6\text{H}_2\text{O}$, as its distribution between the gaseous phase and the crystal obeys the Berthelot-Nernst law: the ratio Rn/SO_2 in crystals is proportional to the corresponding ratio in the gas:

$$\frac{\text{Rn (crys.)}}{\text{SO}_2 \text{ (crys.)}} = D \frac{\text{Rn (gas)}}{\text{SO}_2 \text{ (gas)}}$$

where the constant D for Rn has the value 0.6.

I have also studied the possibility of an isomorphous 'seizure' of argon and neon by the crystals of sulphur dioxide hydrate, when formed from sulphur dioxide and snow at -8° C. I found that argon is held by this hydrate, and could thus be transferred quantitatively from the gaseous phase into the crystals. The partition factor is constant and equal to 0.007. No neon hydrate (or any other compound of neon) is as yet known. Its dissociation pressure is presumably some thousands of atmospheres. Nevertheless, neon is also taken up by the crystals of sulphur dioxide hydrate, though with greater difficulty than argon. Only 1.2 per cent of neon goes into the crystals after passing ninety charges of sulphur dioxide into a tube containing snow and neon at -8° C., each time about 80 per cent of the sulphur dioxide being deposited as hydrate. Under the same conditions only traces of helium, not more than 0.2 per cent, could be found in the crystals. Consequently neon, too, forms a hydrate, isomorphous with the sulphur dioxide hydrate, of the formula $\text{Ne} \cdot 6\text{H}_2\text{O}$; the constant D for neon is of the order of 0.00005.

Different stability of the rare gas hydrates makes it possible to separate them quantitatively by chemical means. After twelve depositions of sulphur dioxide as hydrate of the order of 60-70 per cent each, more than 99 per cent of radon is transferred into the crystals. By means of a current of sulphur dioxide more than 99.5 per cent of helium and neon, and about 90 per cent of argon, may be separated from crystals containing radon. For a quantitative separation of argon and radon, the hydrate must be decomposed and the separation repeated. For quantitative deposition of argon (98 per cent), 160 depositions of sulphur dioxide hydrate (80 per cent each) are needed. The whole operation lasts 8-9 hours. The depositing crystals seize, chemically and mechanically, no more than 0.5 per cent helium and about 3 per cent neon. Consequently, it is possible to separate chemically argon and radon from helium and neon, and radon from argon. It is interesting to note that the chemical properties of argon are nearer to those of radon than to neon.

Proliferation-promoting Substances from Cells injured by Ultra-violet Radiation

As reported in this journal¹ and elsewhere², fractions which stimulate the growth, fermentation and respiration of yeast have been isolated in our laboratories from cells injured by ultra-violet irradiation, X-rays and other means. The following experiments by a new technique have confirmed the production of proliferation-promoting substances by cells injured by ultra-violet radiation.

Reader's medium solidified with agar was cut into blocks 3 mm. × 5 mm. × 5 mm. Dilute suspensions in Reader's medium from cultures of *S. cerevisiae* grown on Sabouraud's slants were applied to the tops of these blocks. Cover glasses were put over the inoculated areas and sealed to the blocks with agar. The materials to be tested for proliferation-promotion were added to the bottoms of the blocks, and the cover glasses and hanging blocks placed on culture slides ringed with 'Vaseline'. The cultures were incubated at room temperature for 24-48 hours. Areas of growth on the tops of the blocks were then recorded by photomicrographs. The proliferation-promoting materials diffused from the bottoms of the blocks to the cells on top, where they caused increased proliferation.

Effects of the following materials were compared: water, Reader's medium, unirradiated and irradiated yeast suspensions, cell-free fractions from unirradiated and irradiated yeast suspensions, and a highly potent bios preparation from malt combings. Yeast suspensions were prepared by adding 3.5 gm. of baker's yeast to 200 c.c. of Ringer's glucose-phosphate solution. Portions of these were irradiated in quartz test tubes, with constant stirring, by the full ultra-violet from a quartz mercury arc until about ninety per cent of the cells were killed. Cell-free fractions were usually prepared by centrifuging the suspensions for 15 minutes and decanting the supernatant fluid, occasionally by filtration through a Berkefeld filter.

In all experiments, growth on blocks to which ultra-violet injured cell suspensions or cell-free fractions from these had been added was much greater

than on blocks to which unirradiated cell suspensions or cell-free fractions therefrom, water, Reader's medium, or nothing had been added. Bios caused approximately the same growth as the irradiated cell-free fractions. The accompanying table summarizes the results and the photomicrographs (Fig. 1) are typical of the 24-hour cultures. Addition of Reader's medium (not included in the table because it was used in only a few experiments) produced no noticeable effect. The apparent stimulation by cell-free fractions from non-irradiated cells seemed to result from mechanical injury to the cells during centrifuging.

SUMMARY OF EXPERIMENTS

Material added to bottom of block	Per cent of area on top covered with growth		Dry weight of material added to block
	After 24-27 hr.	After 47-48 hr.	
Non-irrad. cell suspension	7.1	16.2	0.025 mgm.
Water	7.8	10.5	
Nothing	9.8	20.5	
Cell-free fraction from non-irrad. cells	14.8	no data	0.0011 mgm.
Irrad. cell suspension	30.6	70.2	0.025 mgm.
Cell-free fraction from irrad. cells	27.1	70.2	0.0038 mgm.
Krake's bios prep. No. 14	41.4	no data	0.0087 mgm.

Ultra-violet absorption spectra of cell-free fractions from irradiated and non-irradiated cells showed considerable difference. Those of irradiated fractions were similar to the spectra of proliferation-promoting factors from yeast and irradiated liver cells reported previously².

Fig. 1.

PHOTOMICROGRAPHS OF TOPS OF AGAR BLOCKS AFTER 26 HR. (a) NON-IRRADIATED CELL SUSPENSION ADDED TO BOTTOM OF BLOCK. (b) IRRADIATED CELL SUSPENSION ADDED TO BOTTOM OF BLOCK.

We believe the proliferation-promoting factors produced by ultra-violet injured cells afford a clue to the explanation of wound healing and possibly of certain types of malignancy, as will be discussed more fully elsewhere.

Infra-Red Spectrum of Tetradeuteroethylene

THE molecule C_2D_4 has twelve fundamental modes of vibration, of which six should be observable in Raman scattering, five in infra-red absorption, while the remaining one must be deduced from combination frequencies in the infra-red or from measurements of specific heat. A knowledge of these is of considerable interest in the theory of molecular vibrations (a) as a qualitative check on the assignment of the fundamental frequencies of the C_2H_4 molecule, (b) as a test of various potential functions which have been advanced to correlate the frequencies of C_2H_4 . Of these twelve frequencies, so far only four have been reported, being recently observed in the Raman spectrum by de Hamptinne, Jungers and Delfosse¹. We now wish to report briefly an investigation in the infra-red by which we have identified another four of the twelve fundamentals.
